# Foreword

## 1.1 Purpose

This standard provides an unambiguous definition of the programming language Rexx. Its purpose is to facilitate portability of Rexx programs for use on a wide variety of computer systems.

## 1.2 History

The computer programming language Rexx was designed by Mike Cowlshaw to satisfy the following principal aims:

- to provide a highly readable command programming language for the benefit of programmers and program readers, users and maintainers;
- to incorporate within this language program design features such as natural data typing and control structures which would contribute to rapid, efficient and accurate program development;
- to define a language whose implementations could be both reliable and efficient on a wide variety of computing platforms.

In November, 1990, X3 announced the formation of a new technical committee, X3J18, to develop an American National Standard for Rexx. This standard was published as ANSI X3.274-1996.

The popularity of “Object Oriented” programming, and the need for Rexx to work with objects created in various ways, led to Rexx extensions and to a second X3J18 project which produced this standard. (*Ed - hopefully*)

Committee lists (*Here*)

This standard was prepared by the Technical Development Committee for Rexx, X3J18. There are annexes in this standard; they are informative and are not considered part of this standard.

Suggestions for improvement of this standard will be welcome. They should be sent to the Information Technology Industry Council, 1250 Eye Street, NW, Washington DC 20005-3922.

This standard was processed and approved for submittal to ANSI by the Accredited Standards Committee on Information Processing Systems, NCITS. Committee approval of this standard does not necessarily imply that all committee members voted for its

approval. At the time it approved this standard, the NCITS Committee had the following members:

*To be inserted*

The people who contributed to Technical Committee J18 on Rexx, which developed this standard, include:

## Introduction

This standard provides an unambiguous definition of the programming language Rexx.

## Scope, purpose, and application

### 3.1 Scope

This standard specifies the semantics and syntax of the programming language Rexx by specifying requirements for a conforming language processor. The scope of this standard includes

- the syntax and constraints of the Rexx language;
- the semantic rules for interpreting Rexx programs;
- the restrictions and limitations that a conforming language processor may impose;
- the semantics of configuration interfaces.

This standard does not specify

- the mechanism by which Rexx programs are transformed for use by a data-processing system;
- the mechanism by which Rexx programs are invoked for use by a data-processing system;
- the mechanism by which input data are transformed for use by a Rexx program;
- the mechanism by which output data are transformed after being produced by a Rexx program;
- the encoding of Rexx programs;
- the encoding of data to be processed by Rexx programs;
- the encoding of output produced by Rexx programs;
- the size or complexity of a program and its data that will exceed the capacity of any specific data-processing system or the capacity of a particular language processor;
- all minimal requirements of a data-processing system that is capable of supporting a conforming language processor;
- the syntax of the configuration interfaces.

### 3.2 Purpose

The purpose of this standard is to facilitate portability of Rexx programs for use on a wide variety of configurations.

### 3.3 Application

This standard is applicable to Rexx language processors.

### **3.4 Recommendation**

It is recommended that before detailed reading of this standard, a reader should first be familiar with the Rexx language, for example through reading one of the books about Rexx. It is also recommended that the annexes should be read in conjunction with this standard.

## **Normative references**

There are no standards which constitute provisions of this American National Standard.

## Definitions and document notation

*Lots more for NetRexx*

### 5.1 Definitions

**application programming interface** A set of functions which allow access to some Rexx facilities from non-Rexx programs.

**arguments** The expressions (separated by commas) between the parentheses of a function call or following the name on a CALL instruction. Also the corresponding values which may be accessed by a function or routine, however invoked.

**built-in function** A function (which may be called as a subroutine) that is defined in section nnn of this standard and can be used directly from a program.

**character string** A sequence of zero or more characters.

**clause** A section of the program, ended by a semicolon. The semicolon may be implied by the end of a line or by some other constructs.

**coded** A coded string is a string which is not necessarily comprised of characters. Coded strings can occur as arguments to a program, results of external routines and commands, and the results of some built-in functions, such as D2C.

**command** A clause consisting of just an expression is an instruction known as a command. The expression is evaluated and the result is passed as a command string to some external environment.

**condition** A specific event, or state, which can be trapped by CALL ON or SIGNAL ON.

**configuration** Any data-processing system, operating system and software used to operate a language processor.

**conforming language processor** A language processor which obeys all the provisions of this standard.

**construct** A named syntax grouping, for example “*expression*”, “*do\_specification*”.

**default error stream** An output stream, determined by the configuration, on which error messages are written.

**default input stream** An input stream having a name which is the null string. The use of this stream may be implied.

**default output stream** An output stream having a name which is the null string. The use of this stream may be implied.

**direct symbol** A symbol which, without any modification, names a variable in a variable pool.

**directive** Clauses which begin with two colons are directives. Directives are not executable, they indicate the structure of the program. Directives may also be written with the two colons implied.

**dropped** A symbol which is in an uninitialized state, as opposed to having had a value assigned to it, is described as dropped. The names in a variable pool have an attribute of 'dropped' or 'not-dropped'.

**encoding** The relation between a character string and a corresponding number. The encoding of character strings is determined by the configuration.

**end-of-line** An event that occurs during the scanning of a source program. Normally the end-of-lines will relate to the lines shown if the configuration lists the program. They may, or may not, correspond to characters in the source program.

**environment** The context in which a command may be executed. This is comprised of the environment name, details of the resource that will provide input to the command, and details of the resources that will receive output of the command.

**environment name** The name of an external procedure or process that can execute commands. Commands are sent to the current named environment, initially selected externally but then alterable by using the ADDRESS instruction.

**error number** A number which identifies a particular situation which has occurred during processing. The message prose associated with such a number is defined by this standard.

**exposed** Normally, a symbol refers to a variable in the most recently established variable pool. When this is not the case the variable is referred to as an exposed variable.

**expression** The most general of the constructs which can be evaluated to produce a single string value.

**external data queue** A queue of strings that is external to REXX programs in that other programs may have access to the queue whenever REXX relinquishes control to some other program.

**external routine** A function or subroutine that is neither built-in nor in the same program as the CALL instruction or function call that invokes it.

**external variable pool** A named variable pool supplied by the configuration which can be accessed by the VALUE built-in function.

**function** Some processing which can be invoked by name and will produce a result. This term is used for both REXX functions (See nnn) and functions provided by the configuration (see n).

**identifier** The name of a construct.

**implicit variable** A tailed variable which is in a variable pool solely as a result of an operation on its stem. The names in a variable pool have an attribute of 'implicit' or 'not-implicit'.

**instruction** One or more clauses that describe some course of action to be taken by the language processor.

**internal routine** A function or subroutine that is in the same program as the CALL instruction or function call that invokes it.

**keyword** This standard specifies special meaning for some tokens which consist of letters and have particular spellings, when used in particular contexts. Such tokens, in these contexts, are keywords.

**label** A clause that consists of a single symbol or a literal followed by a colon.

**language processor** Compiler, translator or interpreter working in combination with a configuration.

**notation function** A function with the sole purpose of providing a notation for describing semantics, within this standard. No Rexx program can invoke a notation function.

**null clause** A clause which has no tokens.

**null string** A character string with no characters, that is, a string of length zero.

**production** The definition of a construct, in Backus-Naur form.

**return code** A string that conveys some information about the command that has been executed. Return codes usually indicate the success or failure of the command but can also be used to represent other information.

**routine** Some processing which can be invoked by name.

**state variable** A component of the state of progress in processing a program, described in this standard by a named variable. No Rexx program can directly access a state variable.

**stem** If a symbol naming a variable contains a period which is not the first character, the part of the symbol up to and including the first period is the stem.

**stream** Named streams are used as the sources of input and the targets of output. The total semantics of such a stream are not defined in this standard and will depend on the configuration. A stream may be a permanent file in the configuration or may be something else, for example the input from a keyboard.

**string** For many operations the unit of data is a string. It may, or may not, be comprised of a sequence of characters which can be accessed individually.

**subcode** The decimal part of an error number.

**subroutine** An internal, built-in, or external routine that may or may not return a result string and is invoked by the CALL instruction. If it returns a result string the subroutine can also be invoked by a function call, in which case it is being called as a function.

**symbol** A sequence of characters used as a name, see nnn. Symbols are used to name variables, functions, etc.

**tailed name** The names in a variable pool have an attribute of 'tailed' or 'non-tailed'. Otherwise identical names are distinct if their attributes differ. Tailed names are normally the result of replacements in the tail of a symbol, the part that follows a stem.

**token** The unit of low-level syntax from which high-level constructs are built. Tokens are literal strings, symbols, operators, or special characters.

**trace** A description of some or all of the clauses of a program, produced as each is executed.

**trap** A function provided by the user which replaces or augments some normal function of the language processor.

**variable pool** A collection of the names of variables and their associated values.

## **5.2 Document notation**

### **5.2.1 Rexx Code**

Some Rexx code is used in this standard. This code shall be assumed to have its private set of variables. Variables used in this code are not directly accessible by the program to be processed. Comments in the code are not part of the provisions of this standard.

### **5.2.2 Italics**

Throughout this standard, except in Rexx code, references to the constructs defined in section nnn are *italicized*.

## Conformance

### 6.1 Conformance

A conforming language processor shall not implement any variation of this standard except where this standard permits. Such permitted variations shall be implemented in the manner prescribed by this standard and noted in the documentation accompanying the processor. A conforming processor shall include in its accompanying documentation

- a list of all definitions or values for the features in this standard which are specified to be dependent on the configuration.
- a statement of conformity, giving the complete reference of this standard (ANSI X3.274-1996) with which conformity is claimed.

### 6.2 Limits

Aside from the items listed here (and the assumed limitation in resources of the configuration), a conforming language processor shall not put numerical limits on the content of a program. Where a limit expresses the limit on a number of digits, it shall be a multiple of three. Other limits shall be one of the numbers one, five or twenty five, or any of these multiplied by some power of ten.

Limitations that conforming language processors may impose are:

- `NUMERIC DIGITS` values shall be supported up to a value of at least nine hundred and ninety nine.
- Exponents shall be supported. The limit of the absolute value of an exponent shall be at least as large as the largest number that can be expressed without an exponent in nine digits.
- String lengths shall be supported. The limit on the length shall be at least as large as the largest number that can be expressed without an exponent in nine digits.
- String literal length shall be supported up to at least two hundred and fifty.
- Symbol length shall be supported up to at least two hundred and fifty.

## Configuration

Any implementation of this standard will be functioning within a configuration. In practice, the boundary between what is implemented especially to support Rexx and what is provided by the system will vary from system to system. This clause describes what they shall together do to provide the configuration for the Rexx language processing which is described in this standard.

*We don't want to add undue "magic" to this section. It seems we will need the concept of a "reference" (equivalent to a machine address) so that this section can at least have composite objects as arguments. (As it already does but these are not Rexx objects)*

*Possibly we could unify "reference" with "variable pool number" since object one-to-one with its variable pool is a fair model. That way we don't need a new primitive for comparison of two references.*

*JAVA is only a "reference" for NetRexx so some generalized JAVA-like support is needed for that. It would provide the answers to what classes were in the context, what their method signatures were etc.*

### 7.1 Notation

The interface to the configuration is described in terms of functions. The notation for describing the interface functionally uses the name given to the function, followed by any arguments. This does not constrain how a specific implementation provides the function, nor does it imply that the order of arguments is significant for a specific implementation.

The names of the functions are used throughout this standard; the names used for the arguments are used only in this clause and nnn.

The name of a function refers to its usage. A function whose name starts with

- `Config_` is used only from the language processor when processing programs;
- `API_` is part of the application programming interface and is accessible from programs which are not written in the Rexx language;
- `Trap_` is not provided by the language processor but may be invoked by the language processor.

As its result, each function shall return a completion Response. This is a string indicating how the function behaved. The completion response may be the character 'N' indicating the normal behavior occurred; otherwise the first character is an indicator of a different behavior and the remainder shall be suitable as a human-readable description of the function's behavior.

This standard defines any additional results from `Config_` functions as made available to the language processor in variables. This does not constrain how a particular implementation should return these results.

### 7.1.1 Notation for completion response and conditions

As alternatives to the normal indicator 'N', each function may return a completion response with indicator 'X' or 'S'; other possible indicators are described for each function explicitly. The indicator 'X' means that the function failed because resources were exhausted. The indicator 'S' shows that the configuration was unable to perform the function.

Certain indicators cause conditions to be raised. The possible raising of these conditions is implicit in the use of the function; it is not shown explicitly when the functions are used in this standard.

The implicit action is

```
call #Raise 'SYNTAX', Message, Description
```

where:

- `#Raise` raises the condition, see nnn.
- `Message` is determined by the indicator in the completion response. If the indicator is 'X' then `Message` is 5.1. If the indicator is 'S' then `Message` is 48.1.
- `Description` is the description in the completion response.

The 'SYNTAX' condition 5.1 can also be raised by any other activity of the language processor.

## 7.2 Processing initiation

The processing initiation interface consists of a function which the configuration shall provide to invoke the language processor.

*We could do REQUIRES in a macro-expansion way by adding an argument to `Config_SourceChar` to specify the source file. However, I'm assuming we will prefer to recursively "run" each required file. One of the results of that will be the classes and methods made public by that REQUIRES subject.*

### 7.2.1 API Start

Syntax:

```
API_Start(How, Source, Environment, Arguments, Streams, Traps,  
          Provides)
```

where:

- `How` is one of 'COMMAND', 'FUNCTION', or 'SUBROUTINE' and indicates how the program is invoked.

*What does OOI say for How when running REQUIRED files?*

- **Source** is an identification of the source of the program to be processed.
- **Environment** is the initial value of the environment to be used in processing commands. This has components for the name of the environment and how the input and output of commands is to be directed.
- **Arguments** is the initial argument list to be used in processing. This has components to specify the number of arguments, which arguments are omitted, and the values of arguments that are not omitted.
- **Streams** has components for the default input stream to be used and the default output streams to be used.
- **Traps** is the list of traps to be used in processing (see nnn). This has components to specify whether each trap is omitted or not.

#### **Semantics:**

This function starts the execution of a Rexx program.

If the program was terminated due to a RETURN or EXIT instruction without an expression the completion response is 'N'.

If the program was terminated due to a RETURN or EXIT instruction with an expression the indicator in the completion response is 'R' and the description of the completion response is the value of the expression.

If the program was terminated due to an error the indicator in the completion response is 'E' and the description in the completion response comprises information about the error that terminated processing.

If How was 'REQUIRED' and the completion response was not 'E', the Provides argument is set to reference classes made available. See nnn for the semantics of these classes.

## **7.3 Source programs and character sets**

The configuration shall provide the ability to access source programs (see nnn). Source programs consist of characters belonging to the following categories:

- *syntactic\_characters*;
- *extra\_letters*;
- *other\_blank\_characters*;
- *other\_negators*;
- *other\_characters*.

A character shall belong to only one category.

### **7.3.1 Syntactic\_characters**

The following characters represent the category of characters called *syntactic\_characters*, identified by their names. The glyphs used to represent them in this document are also

shown. *Syntactic\_characters* shall be available in every configuration:

- & ampersand;
- ' apostrophe, single quotation mark, single quote;
- • asterisk, star;
- blank, space;
- A-Z capital letters A through Z;
- : colon;
- , comma;
- 0-9 digits zero through nine;
- = equal sign;
- ! exclamation point, exclamation mark;
- > greater-than sign;
- • hyphen, minus sign;
- < less-than sign;
- [ left bracket, left square bracket;
- ( left parenthesis;
- % percent sign;
- . period, decimal point, full stop, dot;
- • plus sign;
- ? question mark;
- " quotation mark, double quote;
- reverse slant, reverse solidus, backslash;
- ] right bracket, right square bracket;
- ) right parenthesis;
- ; semicolon;
- / slant, solidus, slash;
- a-z small letters a through z;
- ~ tilde, twiddle;
- \_ underline, low line, underscore;
- vertical line, bar, vertical bar.

### 7.3.2 Extra\_letters

A configuration may have a category of characters in source programs called *extra\_letters*. *Extra\_letters* are determined by the configuration.

### 7.3.3 Other\_blank\_characters

A configuration may have a category of characters in source programs called *other\_blank\_characters*. *Other\_blank\_characters* are determined by the configuration. Only the following characters represent possible characters of this category:

- carriage return;
- form feed;

- horizontal tabulation;
- new line;
- vertical tabulation.

#### 7.3.4 Other\_negators

A configuration may have a category of characters in source programs called *other\_negators*. *Other\_negators* are determined by the configuration. Only the following characters represent possible characters of this category. The glyphs used to represent them in this document are also shown:

- $\wedge$  circumflex accent, caret;
- $\neg$  not sign.

#### 7.3.5 Other\_characters

A configuration may have a category of characters in source programs called *other\_characters*. *Other\_characters* are determined by the configuration.

### 7.4 Configuration characters and encoding

The configuration characters and encoding interface consists of functions which the configuration shall provide which are concerned with the encoding of characters.

The following functions shall be provided:

- Config\_SourceChar;
- Config\_OtherBlankCharacters;
- Config\_Upper;
- Config\_Compare;
- Config\_B2C;
- Config\_C2B;
- Config\_Substr;
- Config\_Length;
- Config\_Xrange.

#### 7.4.1 Config\_SourceChar

**Syntax:**

Config\_SourceChar( )

**Semantics:**

Supply the characters of the source program in sequence, together with the *EOL* and *EOS* events. The *EOL* event represents the end of a line. The *EOS* event represents the end of

the source program. The *EOS* event must only occur immediately after an *EOL* event. Either a character or an event is supplied on each invocation, by setting *#Outcome*.

If this function is unable to supply a character because the source program encoding is incorrect the indicator of the completion response is 'E' and the description of the completion information is the encoding which is incorrect, in hexadecimal notation.

### 7.4.2 Config\_OtherBlankCharacters

**Syntax:**

```
call Config OtherBlankCharacters
#AllBlanks<Index "#AllBlanks" # "" > = ' '#Outcome /* "Real" blank
    concatenated with
others */
#Bif Digits. = 9
call Config Constants
.true = '1'
.false = '0'
```

**Semantics:**

Get *other\_blank\_characters* (see nnn).

Set *#Outcome* to a string of zero or more distinct characters in arbitrary order. Each character is one that the configuration considers equivalent to the character *Blank* for the purposes of parsing.

### 7.4.3 Config\_Upper

**Syntax:**

Config\_Upper(Character)

where:

Character is the character to be translated to uppercase.

**Semantics:**

Translate Character to uppercase. Set *#Outcome* to the translated character. Characters which have been subject to this translation are referred to as being in uppercase. Config\_Upper applied to a character in uppercase must not change the character.

### 7.4.4 Config\_Lower

**Syntax:**

Config\_Lower(Character)

where:

Character is the character to be translated to lowercase.

**Semantics:**

Translate Character to lowercase. Set #Outcome to the translated character. Characters which have been subject to this translation are referred to as being in lowercase. Config\_Lower applied to a character in lowercase must not change the character. Config\_Upper of the outcome of Config\_Lower(Character) shall be the original character.

**7.4.5 Config\_Compare****Syntax:**

Config\_Compare(Character1, Character2)

where:

Character1 is the character to be compared with Character2.

Character2 is the character to be compared with Character1.

**Semantics:**

Compare two characters. Set #Outcome to

- 'equal' if Character1 is equal to Character2;
- 'greater' if Character1 is greater than Character2;
- 'lesser' if Character' is less than Character2.
- The function shall exhibit the following characteristics. If Config\_Compare(a,b) produces
  - 'equal' then Config\_Compare(b,a) produces 'equal';
  - 'greater' then Config\_Compare(b,a) produces 'lesser';
  - 'lesser' then Config\_Compare(b,a) produces 'greater';
  - 'equal' and Config\_Compare(b,c) produces 'equal' then Config\_Compare(a,c) produces 'equal';
  - 'greater' and Config\_Compare(b,c) produces 'greater' then Config\_Compare(a,c) produces 'greater';
  - 'lesser' and Config\_Compare(b,c) produces 'lesser' then Config\_Compare(a,c) produces 'lesser';
  - 'equal' then Config\_Compare(a,c) and Config\_Compare(b,c) produce the same value.
- Syntactic characters which are different characters shall not compare equal by Config\_Compare, see nnn.

**7.4.6 Config\_B2C****Syntax:**

Config B2C (Binary)

where:

Binary is a sequence of digits, each '0' or '1'. The number of digits shall be a multiple of eight.

**Semantics:**

Translate Binary to a coded string. Set #Outcome to the resulting string. The string may, or may not, correspond to a sequence of characters.

#### **7.4.7 Config\_C2B**

**Syntax:**

Config C2B (String)

where:

String is a string.

**Semantics:**

Translate String to a sequence of digits, each '0' or '1'. Set #Outcome to the result. This function is the inverse of Config\_B2C.

#### **7.4.8 Config\_Substr**

**Syntax:**

Config Substr(String, n)

where:

String is a string.

n is an integer identifying a position within String.

**Semantics:**

Copy the n-th character from String. The leftmost character is the first character. Set Outcome to the resulting character.

If this function is unable to supply a character because there is no n-th character in String the indicator of the completion response is 'M'.

If this function is unable to supply a character because the encoding of String is incorrect the indicator of the completion response is 'E' and the description of the completion information is the encoding which is incorrect, in hexadecimal notation.

#### **7.4.9 Config Length**

**Syntax:**

Config Length (String)

where:

String is a string.

**Semantics:**

Set #Outcome to the length of the string, that is, the number of characters in the string.

If this function is unable to determine a length because the encoding of String is incorrect, the indicator of the completion response is 'E' and the description of the completion information is the encoding which is incorrect, in hexadecimal notation.

#### **7.4.10 Config\_Xrange**

**Syntax:**

Config Xrange(Character1, Character2)

where:

Character1 is the null string, or a single character.

Character2 is the null string, or a single character.

**Semantics:**

If Character1 is the null string then let LowBound be a lowest ranked character in the character set according to the ranking order provided by Config\_Compare; otherwise let LowBound be Character1.

If Character2 is the null string then let HighBound be a highest ranked character in the character set according to the ranking order provided by Config\_Compare; otherwise let HighBound be Character2. If #Outcome after Config\_Compare(LowBound, HighBound) has a value of

- 'equal' then #Outcome is set to LowBound;
- 'lesser' then #Outcome is set to the sequence of characters between LowBound and HighBound inclusively, in ranking order;
- 'greater' then #Outcome is set to the sequence of characters HighBound and larger, in ranking order, followed by the sequence of characters LowBound and smaller, in ranking order.

## **7.5 Objects**

The objects interface consists of functions which the configuration shall provide for creating objects.

### 7.5.1 Config\_ObjectNew

**Syntax:**

Config ObjectNew

**Semantics:**

Set #Outcome to be a reference to an object. The object shall be suitable for use as a variable pool, see nnn. This function shall never return a value in #Outcome which compares equal with the value returned on another invocation of the function.

### 7.5.2 Config\_Array\_Size

**Syntax:**

Config Array Size(Object, size)

where:

Object is an object.

Size is an integer greater or equal to 0.

**Semantics:**

The configuration should prepare to deal efficiently with the object as an array with indexes having values up to the value of size.

### 7.5.3 Config\_Array\_Put

**Syntax:**

Config Array Put(Array, Item, Index)

where:

Array is an array.

Item is an object

Index is an integer greater or equal to 1.

**Semantics:**

The configuration shall record that the array has Item associated with Index.

### 7.5.4 Config\_Array\_At

**Syntax:**

Config Array At(Array, Index)

where:

Array is an array.

Index is an integer greater or equal to 1.

**Semantics:**

The configuration shall return the item that the array has associated with Index.

### **7.5.5 Config\_Array\_Hasindex**

**Syntax:**

Config Array At(Array, Index)

where:

Array is an array.

Index is an integer greater or equal to 1.

**Semantics:**

Return '1' if there is an item in Array associated with Index, '0' otherwise.

### **7.5.6 Config\_Array\_Remove**

**Syntax:**

Config Array At(Array, Index)

where:

Array is an array.

Index is an integer greater or equal to 1.

**Semantics:**

After this operation, no item is associated with the Index in the Array.

## **7.6 Commands**

The commands interface consists of a function which the configuration shall provide for strings to be passed as commands to an environment.

See nnn and nnn for a description of language features that use commands.

### 7.6.1 Config\_Command

**Syntax:**

Config Command(Environment, Command)

where:

Environment is the environment to be addressed. It has components for:

- the name of the environment;
- the name of a stream from which the command will read its input. The null string indicates use of the default input stream;
- the name of a stream onto which the command will write its output. The null string indicates use of the default output stream. There is an indication of whether writing is to APPEND or REPLACE;
- the name of a stream onto which the command will write its error output. The null string indicates use of the default error output stream. There is an indication of whether writing is to APPEND or REPLACE.

Command is the command to be executed.

**Semantics:**

Perform a command.

- set the indicator to 'E' or 'F' if the command ended with an ERROR condition, or a FAILURE condition, respectively;
- set #RC to the return code string of the command.

## 7.7 External routines

The external routines interface consists of a function which the configuration shall provide to invoke external routines.

See nnn and nnn for a description of the language features that use external routines.

### 7.7.1 Config\_ExternalRoutine

**Syntax:**

Config ExternalRoutine(How, NameType, Name, Environment, Arguments, Streams, Traps) where:

How is one of 'FUNCTION' or 'SUBROUTINE' and indicates how the external routine is to be invoked.

NameType is a specification of whether the name was provided as a symbol or as a string literal. Name is the name of the routine to be invoked.

Environment is an environment value with the same components as on API\_Start.

Arguments is a specification of the arguments to the routine, with the same components as on API\_Start.

Streams is a specification of the default streams, with the same components as on API\_Start.

Traps is the list of traps to be used in processing, with the same components as on API\_Start.

#### **Semantics:**

Invoke an external routine. Set {Outcome to the result of the external routine, or set the indicator of the completion response to 'D' if the external routine did not provide a result.

If this function is unable to locate the routine the indicator of the completion response is 'U'. As a result SYNTAX condition 43.1 is raised implicitly.

If How indicated that a result from the routine was required but the routine did not provide one the indicator of the completion response is 'H'. As a result SYNTAX condition 44.1 is raised implicitly.

If How indicated that a result from the routine was required but the routine provided one that was too long (see #Limit\_String in nnn) the indicator of the completion response is 'L'. As a result SYNTAX condition 52 is raised implicitly.

If the routine failed in a way not indicated by some other indicator the indicator of the completion response is 'F'. As a result SYNTAX condition 40.1 is raised implicitly.

### **7.7.2 Config\_ExternalMethod**

OOI has external classes explicitly via the ::CLASS abc EXTERNAL mechanism. Analogy with classic would also allow the subject of ::REQUIRES to be coded in non-Rexx. However ::REQUIRES subject is coded, we need to gather in knowledge of its method names because of the search algorithm that determines which method is called. Hence reasonable that the ultimate external call is to a method. Perhaps combine Config\_ExternalRoutine with Config\_ExternalMethod.

There is a terminology clash on "environment". Perhaps easiest to change the classic to "address\_environment". (And make it part of new "environment"?)

There are terminology decisions to make about "files", "programs", and "packages". Possibly "program" is the thing you run (and we don't say what it means physically), "file" is a unit of scope (ROUTINES in current file before those in REQUIRED), and "package" we don't use (since a software package from a shop would probably have several files but not everything to run a program.) Using "file" this way may not be too bad since we used "stream" rather than "tile" in the classic definition.

The How parameter will need 'METHOD' as a value. Should API\_Start also allow 'METHOD'. If we pass the new Environment we don't have to pass Streams separately.

Text of Config\_ExternalMethod waiting on such decisions.

**Syntax:**

Config ExternalMethod (How, NameType, Name, Environment, Arguments, Streams, Traps)

where:

How is one of 'FUNCTION' or 'SUBROUTINE' and indicates how the external routine is to be invoked.

NameType is a specification of whether the name was provided as a symbol or as a string literal.

Name is the name of the routine to be invoked.

Environment is an environment value with the same components as on API\_Start.

Arguments is a specification of the arguments to the routine, with the same components as on API\_Start.

Streams is a specification of the default streams, with the same components as on API\_Start.

Traps is the list of traps to be used in processing, with the same components as on API\_Start.

**Semantics:**

Invoke an external routine. Set {Outcome to the result of the external routine, or set the indicator of the completion response to 'D' if the external routine did not provide a result.

If this function is unable to locate the routine the indicator of the completion response is 'U'. As a result SYNTAX condition 43.1 is raised implicitly.

If How indicated that a result from the routine was required but the routine did not provide one the indicator of the completion response is 'H'. As a result SYNTAX condition 44.1 is raised implicitly.

If How indicated that a result from the routine was required but the routine provided one that was too long (see #Limit\_String in nnn) the indicator of the completion response is 'L'. As a result SYNTAX condition 52 is raised implicitly.

If the routine failed in a way not indicated by some other indicator the indicator of the completion response is 'F'. As a result SYNTAX condition 40.1 is raised implicitly.

## 7.8 External data queue

The external data queue interface consists of functions which the configuration shall provide to manipulate an external data queue mechanism.

See nnn, nnn, nnn, nnn, and nnn for a description of language features that use the external data queue. The configuration shall provide an external data queue mechanism. The following functions shall be provided:

- Config\_Push;

- Config\_Queue;
- Config\_Pull;
- Config\_Queueed.

The configuration may permit the external data queue to be altered in other ways. In the absence of such alterations the external data queue shall be an ordered list. Config\_Push adds the specified string to one end of the list, Config\_Queue to the other. Config\_Pull removes a string from the end that Config\_Push adds to unless the list is empty.

### 7.8.1 Config Push

**Syntax:**

Config Push(String)

where:

String is the value to be retained in the external data queue.

**Semantics:**

Add String as an item to the end of the external data queue from which Config\_Pull will remove an item.

### 7.8.2 Config\_Queue

**Syntax:**

Config Queue (String)

where:

String is the value to be retained in the external data queue.

**Semantics:**

Add String as an item to the opposite end of the external data queue from which Config\_Pull will remove an item.

### 7.8.3 Config\_Pull

**Syntax:**

Config Pull()

**Semantics:**

Retrieve an item from the end of the external data queue to which Config\_Push adds an element to the list. Set #Outcome to the value of the retrieved item.

If no item could be retrieved the indicator of the completion response is 'F'.

#### 7.8.4 Contig\_Queued

**Syntax:**

Config Queued ()

**Semantics:**

Get the count of items in the external data queue. Set #Outcome to that number.

### 7.9 Streams

The streams interface consists of functions which the configuration shall provide to manipulate streams. See nnn, nnn, and nnn for a description of language features which use streams.

Streams are identified by names and provide for the reading and writing of data. They shall support the concepts of characters, lines, positioning, default input stream and default output stream.

The concept of a persistent stream shall be supported and the concept of a transient stream may be supported. A persistent stream is one where the content is not expected to change except when the stream is explicitly acted on. A transient stream is one where the data available is expected to vary with time.

The concepts of binary and character streams shall be supported. The content of a character stream is expected to be characters.

The null string is used as a name for both the default input stream and the default output stream. The null string names the default output stream only when it is an argument to the Config\_Stream\_Charout operation.

The following functions shall be provided:

- Config\_Stream\_Charin;
- Config\_Stream\_Position;
- Config\_Stream\_Command;
- Config\_Stream\_State;
- Config\_Stream\_Charout;
- Config\_Stream\_Qualified;
- Config\_Stream\_Unique;
- Config\_Stream\_Query;
- Config\_Stream\_Close;
- Config\_Stream\_Count.
- The results of these functions are described in terms of the following stems with tails which are stream names:
  - #Charin\_Position.Stream;
  - #Charout\_Position.Stream;
  - #Linein\_Position.Stream;
  - #Lineout\_Position.Stream.

### 7.9.1 Config\_Stream\_Charin

**Syntax:**

Config Stream Charin(Stream, OperationType)

where:

Stream is the name of the stream to be processed.

OperationType is one of 'CHARIN', 'LINEIN', or 'NULL'.

**Semantics:**

Read from a stream. Increase #Linein\_Position.Stream by one when the end-of-line indication is encountered. Increase #Charin\_Position.Stream when the indicator will be 'N'.

If OperationType is 'CHARIN' the state variables describing the stream will be affected as follows: - when the configuration is able to provide data from a transient stream or the character at position #Charin\_Position.Stream of a persistent stream then #Outcome shall be set to contain the data.

The indicator of the response shall be 'N';

- when the configuration is unable to return data because the read position is at the end of a persistent stream then the indicator of the response shall be 'O';
- when the configuration is unable to return data from a transient stream because no data is available and no data is expected to become available then the indicator of the response shall be 'O';
- otherwise the configuration is unable to return data and does not expect to be able to return data by waiting; the indicator of the response shall be 'E'. The data set in #Outcome will either be a single character or will be a sequence of eight characters, each '0' or '1'. The choice is decided by the configuration. The eight character sequence indicates a binary stream, see nnn.

If OperationType is 'LINEIN' then the action is the same as if Operation had been 'CHARIN' with the following additional possibility. If end-of-line is detected any character (or character sequence) which is an embedded indication of the end-of-line is skipped. The characters skipped contribute to the change of #Charin\_Position.Stream. #Outcome is the null string.

If OperationType is 'NULL' then the stream is accessed but no data is read.

### 7.9.2 Config\_Stream\_Position

**Syntax:**

Config Stream Position(Stream, OperationType, Position)

where:

Stream is the name of the stream to be processed.

Operation is 'CHARIN', 'LINEIN', 'CHAROUT', or 'LINEOUT'.

Position indicates where to position the stream.

**Semantics:**

If the operation is 'CHARIN' or 'CHAROUT' then Position is a character position, otherwise Position is a line position.

If Operation is 'CHARIN' or 'LINEIN' and the Position is beyond the limit of the existing data then the indicator of the completion response shall be 'R'. Otherwise if Operation is 'CHARIN' or 'LINEIN' set #Charin\_Position.Stream to the position from which the next Config\_Stream\_Charin on the stream shall read, as indicated by Position. Set #Linein\_Position.Stream to correspond with this position.

If Operation is 'CHAROUT' or 'LINEOUT' and the Position is more than one beyond the limit of existing data then the indicator of the response shall be 'R'. Otherwise if Operation is 'CHAROUT' or 'LINEOUT' then #Charout\_Position.Stream is set to the position at which the next Config\_Stream\_Charout on the stream shall write, as indicated by Position. Set #Lineout\_Position.Stream to correspond with this position.

If this function is unable to position the stream because the stream is transient then the indicator of the completion response shall be 'T'.

### 7.9.3 Config\_Stream\_Command

**Syntax:**

Config Stream Command (Stream, Command) where: Stream is the name of the stream to be processed. Command is a configuration-specific command to be performed against the stream.

**Semantics:**

Issue a configuration-specific command against a stream. This may affect all state variables describing Stream which hold position information. It may alter the effect of any subsequent operation on the specified stream. If the indicator is set to 'N', #Outcome shall be set to information from the command.

### 7.9.4 Config\_Stream\_State

**Syntax:**

Config Stream State (Stream) where: Stream is the name of the stream to be queried.

**Semantics:**

Set the indicator to reflect the state of the stream. Return an indicator equal to the indicator that an immediately subsequent Config\_Stream\_Charin(Stream, 'CHARIN')

would return. Alternatively, return an indicator of 'U'.

The remainder of the response shall be a configuration-dependent description of the state of the stream.

### 7.9.5 Config\_Stream\_Charout

**Syntax:**

Config Stream Charout (Stream, Data) where: Stream is the name of the stream to be processed. Data is the data to be written, or 'EOL' to indicate that an end-of-line indication is to be written, or a null string. In the first case, if the stream is a binary stream then Data will be eight characters, each '0' or '1', otherwise Data will be a single character.

**Semantics:**

When Data is the null string, no data is written. Otherwise write to the stream. The state variables describing the stream will be affected as follows:

- when the configuration is able to write Data to a transient stream or at position #Charout\_Position.Stream of a persistent stream then the indicator in the response shall be 'N'. When Data is not 'EOL' then #Charout\_Position.Stream is increased by one. When Data is 'EOL', then #Lineout\_Position.Stream is increased by one and #Charout\_Position.Stream is increased as necessary to account for any end-of-line indication embedded in the stream;
- when the configuration is unable to write Data the indicator is set to 'E'.

### 7.9.6 Config\_Stream\_Qualified

**Syntax:**

Config Stream Qualified (Stream) where: Stream is the name of the stream to be processed.

**Semantics:**

Set #Outcome to some name which identifies Stream. Return a completion response with indicator 'B' if the argument is not acceptable to the configuration as identifying a stream.

### 7.9.7 Config\_Stream\_Unique

**Syntax:**

Config Stream Unique ()

**Semantics:**

Set #Outcome to a name that the configuration recognizes as a stream name. The name shall not be a name that the configuration associates with any existing data.

**7.9.8 Config\_Stream\_Query****Syntax:**

Config Stream Query (Stream) where: Stream is the name of the stream to be queried.

**Semantics:**

Set #Outcome to 'B' if the stream is a binary stream, or to 'C' if it is a character stream.

**7.9.9 Config\_Stream\_Close****Syntax:**

Config Stream Close (Stream) where: Stream is the name of the stream to be closed.

**Semantics:**

#Charout\_Position.Stream and #Lineout\_Position.Stream are set to 1 unless the stream has existing data, in which case they are set ready to write immediately after the existing data. If this function is unable to position the stream because the stream is transient then the indicator of the completion response shall be 'T'.

**7.9.10 Config\_Stream\_Count****Syntax:**

Config Stream Count (Stream, Operation, Option) where: Stream is the name of the stream to be counted. Operation is 'CHARS', or 'LINES'.

Option is 'N' or 'C'.

**Semantics:**

If the option is 'N', #Outcome is set to zero if:

- the file is transient and no more characters (or no more lines if the Operation is 'LINES') are expected to be available, even after waiting;
- the file is persistent and no more characters (or no more lines if the Operation is 'LINES') can be obtained from this stream by Config\_Stream\_Charin before use of some function which resets #Charin\_Position.Stream and #Linein\_Position.Stream.

If the option is 'N' and #Outcome is set nonzero, #Outcome shall be 1, or be the number of characters (or the number of lines if Operation is 'LINES') which could be read from the stream before resetting.

If the option is 'C', #Outcome is set to zero if:

- the file is transient and no characters (or no lines if the Operation is 'LINES') are available without waiting;
- the file is persistent and no more characters (or no more lines if the Operation is 'LINES') can be obtained from this stream by Config\_Stream\_Charin before use of some function which resets #Charin\_Position.Stream and #Linein\_Position.Stream. If the option is 'C' and #Outcome is set nonzero, #Outcome shall be the number of characters (or the number of lines if the Operation is 'LINES') which can be read from the stream without delay and before resetting.

## 7.10 External variable pools

The external variable pools interface consists of functions which the configuration shall provide to manipulate variables in external variable pools.

See nnn for the VALUE built-in function which uses external variable pools.

The configuration shall provide an external variable pools mechanism. The following functions shall be provided:

- Config\_Get;
- Config\_Set.

The configuration may permit the external variable pools to be altered in other ways.

### 7.10.1 Config Get

**Syntax:**

Config Get (Poolid, Name)

where:

Poolid is an identification of the external variable pool.

Name is the name of a variable.

**Semantics:**

Get the value of a variable with name Name in the external variable pool Poolid. Set Outcome to this value.

If Poolid does not identify an external pool provided by this configuration, the indicator of the completion response is 'P'.

If Name is not a valid name of a variable in the external pool, the indicator of the completion response is 'F'.

### 7.10.2 Config Set

**Syntax:**

Config Set (Poolid, Name, Value)

where:

Poolid is an identification of the external variable pool.

Name is the name of a variable.

Value is the value to be assigned to the variable.

**Semantics:**

Set a variable with name Name in the external variable pool Poolid to Value.

If Poolid does not identify an external pool provided by this configuration, the indicator of the completion response is 'P'.

If Name is not a valid name of a variable in the external pool, the indicator of the completion response is 'F'.

## 7.11 Configuration characteristics

The configuration characteristics interface consists of a function which the configuration shall provide which indicates choices decided by the configuration.

### 7.11.1 Config\_Constants

**Syntax:**

Config Constants ()

**Semantics:**

Set the values of the following state variables:

- if there are any built-in functions which do not operate at NUMERIC DIGITS 9, then set variables #Bif\_Digits. (with various tails which are the names of those built-in functions) to the values to be used;
- set variables #Limit\_Digits, #Limit\_EnvironmentName, #Limit\_ExponentDigits, #Limit\_Literal, #Limit\_MessageInsert, #Limit\_Name, #Limit\_String, #Limit\_TraceData to the relevant limits. A configuration shall allow a #Limit\_MessageInsert value of 50 to be specified. A configuration shall allow a #Limit\_TraceData value of 250 to be specified;
- set #Configuration to a string identifying the configuration;
- set #Version to a string identifying the language processor. It shall have five words. Successive words shall be separated by a blank character. The first four letters of the

first word shall be 'REXX'. The second word shall be the four characters '5.00'. The last three words comprise a date. This shall be in the format which is the default for the DATE() built-in function.

- set .nil to a value which compares unequal with any other value that can occur in execution.
- set .local .kernel .system?

## 7.12 Configuration routines

The configuration routines interface consists of functions which the configuration shall provide which provide functions for a language processor.

The following functions shall be provided:

- Config\_Trace\_Query;
- Config\_Trace\_Input;
- Config\_Trace\_Output;
- Config\_Default\_Input;
- Config\_Default\_Output;
- Config\_Initialization;
- Config\_Termination;
- Config\_Halt\_Query;
- Config\_Halt\_Reset;
- Config\_NoSource;
- Config\_Time;
- Config\_Random\_Seed;
- Config\_Random\_Next.

### 7.12.1 Config\_Trace\_Query

**Syntax:**

Config Trace Query ()

**Semantics:**

Indicate whether external activity is requesting interactive tracing. Set #Outcome to 'Yes' if interactive tracing is currently requested. Otherwise set #Outcome to 'No'.

### 7.12.2 Config\_Trace\_Input

**Syntax:**

Config Trace Input ()

**Semantics:**

Set #Outcome to a value from the source of trace input. The source of trace input is determined by the configuration.

**7.12.3 Config\_Trace\_Output****Syntax:**

Config Trace Output (Line)

where:

Line is a string.

**Semantics:**

Write String as a line to the destination of trace output. The destination of trace output is defined by the configuration.

**7.12.4 Config\_Default\_Input****Syntax:**

Config Default Input ()

**Semantics:**

Set #Outcome to the value that LINEIN( ) would return.

**7.12.5 Config\_Default\_Output****Syntax:**

Config Default Output (Line)

where:

Line is a string.

**Semantics:**

Write the string as a line in the manner of LINEOUT( ,Line).

**7.12.6 Config\_Initialization****Syntax:**

Config Initialization ()

**Semantics:**

This function is provided only as a counterpart to Trap\_Initialization; in itself it does nothing except return the response. An indicator of 'F' gives rise to Msg3.1.

**7.12.7 Config\_Termination****Syntax:**

Config Termination ()

**Semantics:**

This function is provided only as a counterpart to Trap\_Termination; in itself it does nothing except return the response. An indicator of 'F' gives rise to Msg2.1.

**7.12.8 Config\_Halt\_Query****Syntax:**

Config Halt Query ()

**Semantics:**

Indicate whether external activity has requested a HALT condition to be raised. Set #Outcome to 'Yes if HALT is requested. Otherwise set #Outcome to 'No'.

**7.12.9 Config\_Halt\_Reset****Syntax:**

Config Halt Reset ()

**Semantics:**

Reset the configuration so that further attempts to cause a HALT condition will be recognized.

**7.12.10 Config\_NoSource****Syntax:**

Config NoSource ()

**Semantics:**

Indicate whether the source of the program may or may not be output by the language processor. Set #NoSource to '1' to indicate that the source of the program may not be output by the language processor, at various points in processing where it would otherwise be output. Otherwise, set #NoSource to '0'.

A configuration shall allow any program to be processed in such a way that Config\_NoSource() sets #NoSource to '0'. A configuration may allow any program to be processed in such a way that Config\_NoSource() sets #NoSource to '1'.

**7.12.11 Config\_Time****Syntax:**

Config Time ()

**Semantics:**

Get a time stamp. Set #Time to a string whose value is the integer number of microseconds that have elapsed between 00:00:00 on January first 0001 and the time that Config\_Time is called, at longitude zero. Values sufficient to allow for any date in the year 9999 shall be supported. The value returned may be an approximation but shall not be smaller than the value returned by a previous use of the function.

Set #Adjust<Index "#Adjust" # " "> to an integer number of microseconds. #Adjust<Index "#Adjust" # " "> reflects the difference between the local date/time and the date/time corresponding to #Time. #Time + #Adjust<Index "#Adjust" # " "> is the local date/time.

**7.12.12 Config\_Random\_Seed****Syntax:**

Config Random Seed (Seed)

where:

Seed is a sequence of up to #Bif\_Digits. RANDOM digits.

**Semantics:**

Set a seed, so that subsequent uses of Config\_Random\_Next will reproducibly return quasi-random numbers.

**7.12.13 Config\_Random\_Next****Syntax:**

Config Random Next (Min, Max)

where:

Min is the lower bound, inclusive, on the number returned in #Outcome.

Max is the upper bound, inclusive, on the number returned in #Outcome.

**Semantics:**

Set #Outcome to a quasi-random nonnegative integer in the range Min to Max.

#### **7.12.14 Config\_Options**

**Syntax:**

Config\_Options (String)

where:

String is a string.

**Semantics:**

No effect beyond the effects common to all Config\_ invocations. The value of the string will have come from an OPTIONS instruction, see nnn.

### **7.13 Traps**

The trapping interface consists of functions which may be provided by the caller of API\_Start (see nnn) as a list of traps. Each trap may be specified or omitted. The language processor shall invoke a specified trap before, or instead of, using the corresponding feature of the language processor itself. This correspondence is implied by the choice of names; that is, a name beginning Trap\_ will correspond to a name beginning Config\_ when the remainder of the name is the same. Corresponding functions are called with the same interface, with one exception. The exception is that a trap may return a null string. When a trap returns a null string, the corresponding Config\_ function is invoked; otherwise the invocation of the trap replaces the potential invocation of the Config\_ function.

In the rest of this standard, the trapping mechanism is not shown explicitly. It is implied by the use of a Config\_ function.

The names of the traps are

- Trap\_Command;
- Trap\_ExternalRoutine;
- Trap\_Push;
- Trap\_Queue;
- Trap\_Pull;
- Trap\_Queued;
- Trap\_Trace\_Query;

- Trap\_Trace\_Input;
- Trap\_Trace\_Output;
- Trap\_Default\_Input;
- Trap\_Default\_Output;
- Trap\_Initialization;
- Trap\_Termination;
- Trap\_Halt\_Query;
- Trap\_Halt\_Reset.

## 7.14 Variable pool

How does this fit with variables as properties?

The variable pool interface consists of functions which the configuration shall provide to manipulate the variables and to obtain some characteristics of a Rexx program.

These functions can be called from programs not written in Rexx \_ commands and external routines invoked from a Rexx program, or traps invoked from the language processor.

All the functions comprising the variable pool interface shall return with an indication of whether an error occurred. They shall return indicating an error and have no other effect, if #API\_Enabled has a value of '0' or if the arguments to them fail to meet the defined syntactic constraints.

These functions interact with the processing of clauses. To define this interaction, the functions are described here in terms of the processing of variables, see nnn.

Some of these functions have an argument which is a symbol. A symbol is a string. The content of the string shall meet the syntactic constraints of the left hand side of an assignment. Conversion to uppercase and substitution in compound symbols occurs as it does for the left hand side of an assignment. The symbol identifies the variable to be operated upon.

Some of the functions have an argument which is a direct symbol. A direct symbol is a string. The content of this string shall meet the syntactic constraints of a VAR\_SYMBOL in uppercase with no periods or it shall be the concatenation of a part meeting the syntactic constraints of a stem in uppercase, and a part that is any string. In the former case the symbol identifies the variable to be operated upon. In the latter case the variable to be operated on is one with the specified stem and a tail which is the remainder of the direct symbol.

Functions that have an argument which is symbol or direct symbol shall return an indication of whether the identified variable existed before the function was executed. Clause nnn defines functions which manipulate Rexx variable pools. Where possible the functions comprising the variable pool interface are described in terms of the appropriate invocations of the functions defined in nnn. The first parameter on these calls is the state variable #Pool. If these Var\_ functions do not return an indicator 'N', 'R', or 'D' then the API function shall return an error indication.

### 7.14.1 API Set

**Syntax:**

API Set(Symbol, Value)

where:

Symbol is a symbol.

Value is the string whose value is to be assigned to the variable.

**Semantics:**

Assign the value of Value to the variable identified by Symbol. If Symbol contains no periods or contains one period as its last character: Var\_Set(#Pool, Symbol, '0', Value) Otherwise: Var\_Set(#Pool, #Symbol, '1', Value) where: #Symbol is Symbol after any replacements in the tail as described by nnn.

### 7.14.2 API Value

**Syntax:**

API Value (Symbol)

where:

Symbol is a symbol.

**Semantics:**

Return the value of the variable identified by Symbol. If Symbol contains no periods or contains one

period as its last character this is the value of #Outcome after: Var\_Value(#Pool, Symbol, '0')

Otherwise the value of #Outcome after: Var\_Value(#Pool, #Symbol, '1')

where:

#Symbol is Symbol after any replacements in the tail as described by nnn.

### 7.14.3 API\_Drop

**Syntax:**

API Drop (Symbol)

where:

Symbol is a symbol.

**Semantics:**

Drop the variable identified by Symbol. If Symbol contains no periods or contains one period as its last character: Var Drop(#Pool, Symbol, '0') Otherwise: Var Drop(#Pool, #Symbol, '1') where: #Symbol is Symbol after any replacements in the tail as described by nnn.

**7.14.4 API SetDirect****Syntax:**

API SetDirect (Symbol, Value)

where: Symbol is a direct symbol. Value is the string whose value is to be assigned to the variable.

**Semantics:**

Assign the value of Value to the variable identified by Symbol. If the Symbol contains no period: Var\_ Set(#Pool, Symbol, '0', Value)

Otherwise: Var\_ Set(#Pool, Symbol, '1', Value)

**7.14.5 API\_ValueDirect****Syntax:**

API ValueDirect (Symbol)

where: Symbol is a direct symbol.

**Semantics:**

Return the value of the variable identified by Symbol. If the Symbol contains no period: Var \_Value(#Pool, Symbol, '0') Otherwise: Var \_Value(#Pool, Symbol, '1')

**7.14.6 API DropDirect****Syntax:**

API DropDirect (Symbol)

where: Symbol is a direct symbol.

**Semantics:**

Drop the variable identified by Symbol. If the Symbol contains no period: Var Drop(#Pool, Symbol, '0')

Otherwise: Var Drop(#Pool, Symbol, '1')

### 7.14.7 API ValueOther

**Syntax:**

API ValueOther (Qualifier) where: Qualifier is an indication distinguishing the result to be returned including any necessary further qualification.

**Semantics:**

Return characteristics of the program, depending on the value of Qualifier. The possibilities for the value to be returned are:

- the value of #Source;
- the value of #Version;
- the largest value of n such that #ArgExists.1.n is '1', see nnn;
- the value of #Arg.1.n where n is an integer value provided as input.

### 7.14.8 API Next

**Syntax:**

API Next ()

**Semantics:**

Returns both the name and the value of some variable in the variable pool that does not have the attribute 'dropped' or the attribute 'implicit' and is not a stem; alternatively return an indication that there is no suitable name to return. When API\_Next is called it will return a name that has not previously been returned; the order is undefined. This process of returning different names will restart whenever the Rexx processor executes Var\_Reset.

### 7.14.9 API\_NextVariable

**Syntax:**

API\_NextVariable( )

**Semantics:**

Returns both the name and the value of some variable in the variable pool that does not have the attribute 'dropped' or the attribute 'implicit'; alternatively, return an indication that there is no suitable name to return. When API\_NextVariable is called it will return data about a variable that has not previously been returned; the order is undefined. This process of returning different names will restart whenever the Rexx processor executes Var\_Reset. In addition to the name and value, an indication of whether the variable was 'tailed' will be returned.

## Syntax constructs

### 8.1 Notation

#### 8.1.1 Backus-Naur Form (BNF)

The syntax constructs in this standard are defined in Backus-Naur Form (BNF). The syntax used in these BNF productions has

- a left-hand side (called *identifier*);
- the characters ' : = ';
- a right-hand side (called *bnf\_expression*).

The left-hand side identifies syntactic constructs. The right-hand side describes valid ways of writing a specific syntactic construct.

The right-hand side consists of operands and operators, and may be grouped.

#### 8.1.2 Operands

Operands may be terminals or non-terminals. If an operand appears as identifier in some other production it is called a non-terminal, otherwise it is called a terminal. Terminals are either literal or symbolic.

Literal terminals are enclosed in quotes and represent literally (apart from case) what must be present in the source being described.

Symbolic terminals formed with lower case characters represent something which the configuration may, or may not, allow in the source program, see nnn, nnn, nnn, nnn.

Symbolic terminals formed with uppercase characters represent events and tokens, see nnn and nnn.

#### 8.1.3 Operators

The following lists the valid operators, their meaning, and their precedence; the operator listed first has the highest precedence; apart from precedence recognition is from left to right:

- the postfix plus operator specifies one or more repetitions of the preceding construct;
- abuttal specifies that the preceding and the following construct must appear in the given order;

- the operator '|' specifies alternatives between the preceding and the following constructs.

#### 8.1.4 Grouping

Parentheses and square brackets are used to group constructs. Parentheses are used for the purpose of grouping only. Square brackets specify that the enclosed construct is optional.

#### 8.1.5 BNF syntax definition

The BNF syntax, described in BNF, is:

```
production := identifier ':=' bnf_expression
bnf_expression := abuttal | bnf_expression '|' abuttal
abuttal := [abuttal] bnf_primary
bnf_primary := '[' bnf_expression ']' | '(' bnf_expression ')' |
             literal |
             identifier | message identifier | bnf_primary '+'
```

#### 8.1.6 Syntactic errors

The syntax descriptions (see nnn and nnn) make use of *message\_identifiers* which are shown as Msgnn.nn or Msgnn, where nn is a number. These actions produce the correspondingly numbered error messages (see nnn and nnn).

## 8.2 Lexical

The lexical level processes the source and provides tokens for further recognition by the top syntax level.

#### 8.2.1 Lexical elements

##### Events

The fully-capitalized identifiers in the BNF syntax (see nnn) represent events. An event is either supplied by the configuration or occurs as result of a look-ahead in left-to-right parsing. The following events are defined:

- *EOL* occurs at the end of a line of the source. It is provided by Config\_SourceChar, see nnn;
- *EOS* occurs at the end of the source program. It is provided by Config\_SourceChar;
- *RADIX* occurs when the character about to be scanned is 'X' or 'x' or 'B' or 'b' not followed by a *general\_letter*, or a *digit*, or ' . ';
- *CONTINUE* occurs when the character about to be scanned is ' , ' , and the characters after the ' , ' up to *EOL* represent a repetition of *comment* or *blank*, and the *EOL* is not immediately followed by an *EOS*;

- *EXPONENT\_SIGN* occurs when the character about to be scanned is '+' or '-', and the characters to the left of the sign, currently parsed as part of *Const\_symbol*, represent a *plain\_number* followed by 'E' or 'e', and the characters to the right of the sign represent a repetition of *digit* not followed by a *general\_letter* or '.'.

- I would put ASSIGN here for the leftmost '=' in a clause that is not within parentheses or brackets. But Simon not happy with message term being an assignment?

### **Actions and tokens**

Mixed case identifiers with an initial capital letter cause an action when they appear as operands in a production. These actions perform further tests and create tokens for use by the top syntax level. The following actions are defined:

- Special supplies the source recognized as special to the top syntax level;
- Eol supplies a semicolon to the top syntax level;
- Eos supplies an end of source indication to the top syntax level;
- Var\_symbol supplies the source recognized as Var\_symbol to the top syntax level, as keywords or VAR\_SYMBOL tokens, see nnn. The characters in a Var\_symbol are converted by Config\_Upper to uppercase. Msg30.1 shall be produced if Var\_symbol/ contains more than #Limit\_Name characters, see nnn;
- Const\_symbol supplies the source recognized as Const\_symbol! to the top syntax level. If it is a number it is passed as a NUMBER token, otherwise it is passed as a CONST\_SYMBOL token. The characters in a Const\_symbol are converted by Config\_Upper to become the characters that comprise that NUMBER or CONST\_SYMBOL. Msg30.1 shall be produced if Const\_symbol! contains more than #Limit\_Name characters;
- Embedded\_quotation\_mark records an occurrence of two consecutive quotation marks within a string delimited by quotation marks for further processing by the String action;
- Embedded\_apostrophe records an occurrence of two consecutive apostrophes within a string delimited by apostrophes for further processing by the String action;
- String supplies the source recognized as String to the top syntax level as a STRING token. Any occurrence of Embedded\_quotation\_mark or Embedded\_apostrophe is replaced by a single quotation mark or apostrophe, respectively. Msg30.2 shall be produced if the resulting string contains more than #Limit\_Literal characters;
- Binary\_string supplies the converted binary string to the top syntax level as a STRING token, after checking conformance to the binary\_string syntax. If the binary\_string does not contain any occurrence of a binary\_digit, a string of length 0 is passed to the top syntax level. The occurrences of binary\_digit are concatenated to form a number in radix 2. Zero or 4 digits are added at the left if necessary to make the number of digits a multiple of 8. If the resulting number of digits exceeds 8 times #Limit\_Literal then Msg30.2 shall be produced. The binary digits are converted to an encoding, see nnn. The encoding is supplied to the top syntax level as a STRING token;
- Hex\_string supplies the converted hexadecimal string to the top syntax level as a STRING token, after checking conformance to the hex\_string syntax. If the

hex\_string does not contain any occurrence of a hex\_digit, a string of length 0 is passed to the top syntax level. The occurrences of hex\_digit are each converted to a number with four binary digits and concatenated. 0 to 7 digits are added at the left if necessary to make the number of digits a multiple of 8. If the resulting number of digits exceeds 8 times #Limit\_Literal then Msg30.2 shall be produced. The binary digits are converted to an encoding. The encoding is supplied to the top syntax level as a STRING token;

- Operator supplies the source recognized as Operator (excluding characters that are not operator\_char ) to the top syntax level. Any occurrence of an other\_negator within Operator is supplied as ”;
- Blank records the presence of a blank. This may subsequently be tested (see nnn). Constructions of type Number, Const\_symbol, Var\_symbol or String are called operands. 6.2.1.3 Source characters The source is obtained from the configuration by the use of Config\_SourceChar (see nnn). If no character is available because the source is not a correct encoding of characters, message Msg22.1 shall be produced. The terms extra\_letter, other\_blank\_character, other\_negator, and other\_character used in the productions of the lexical level refer to characters of the groups extra\_letters (see nnn),

other\_blank\_characters (see nnn), other\_negators (see nnn) and other\_characters (see nnn), respectively.

## Rules

In scanning, recognition that causes an action (see nnn) only occurs if no other recognition is possible, except that Embedded\_apostrophe and Embedded\_quotation\_mark actions occur wherever possible.

### 8.2.2 Lexical level

### 8.2.3 Interaction between levels of syntax

When the lexical process recognizes tokens to be supplied to the top level, there can be changes made or tokens added. Recognition is performed by the lexical process and the top level process in a synchronized way. The tokens produced by the lexical level can be affected by what the top level syntax has recognized. Those tokens will affect subsequent recognition by the top level. Both processes operate on the characters and the tokens in the order they are produced. The term “context” refers to the progress of the recognition at some point, without consideration of unprocessed characters and tokens. If a token which is ‘+’, ‘-’, ‘ ’ or ‘(’ appears in a lexical level context (other than after the keyword ‘PARSE’) where the keyword ‘VALUE’ could appear in the corresponding top level context, then ‘VALUE’ is passed to the top level before the token is passed. If an ‘=’ operator\_char appears in a lexical level context where it could be the ‘=’ of an assignment or message\_instruction in the corresponding top level context then it is recognized as the ‘=’ of that instruction. (It will be outside of brackets and parentheses, and any Var\_symbol immediately preceding it is passed as a VAR\_SYMBOL). If an operand is followed by a colon token in the lexical level context then the operand only is passed to

the top level syntax as a LABEL, provided the context permits a LABEL. Except where the rules above determine the token passed, a Var\_symbol is passed as a terminal (a keyword) rather than as a VAR\_SYMBOL under the following circumstances:

- if the symbol is spelled 'WHILE' or 'UNTIL' it is a keyword wherever a VAR\_SYMBOL would be part of an expression within a do\_specification,
- if the symbol is spelled 'TO' , 'BY', or 'FOR' it is a keyword wherever a VAR\_SYMBOL would be part of an expression within a do\_rep;
- if the symbol is spelled 'WITH' it is a keyword wherever a VAR\_SYMBOL would be part of a parsevalue, or part of an expression or taken\_constant within address;
- if the symbol is spelled 'THEN' it is keyword wherever a VAR\_SYMBOL would be part of an expression immediately following the keyword 'IF' or 'WHEN'. Except where the rules above determine the token passed, a Var\_symbol is passed as a keyword if the spelling of it matches a keyword which the top level syntax recognizes in its current context, otherwise the Var\_symbol is passed as a VAR\_SYMBOL token. In a context where the top level syntax could accept a '||' token as the next token, a '||' operator or a ' ' operator may be inferred and passed to the top level provided that the next token from the lexical level is a left parenthesis or an operand that is not a keyword. If the blank action has recorded the presence of one or more blanks to the left of the next token then the ' ' operator is inferred. Otherwise, a '||' operator is inferred, except if the next token is a left parenthesis following an operand (see nnn); in this case no operator is inferred. When any of the keywords 'OTHERWISE', 'THEN', or 'ELSE' is recognized, a semicolon token is supplied as the following token. A semicolon token is supplied as the previous token when the 'THEN' keyword is recognized. A semicolon token is supplied as the token following a LABEL.

#### **Reserved symbols**

A Const\_symbol which starts with a period and is not a Number shall be spelled .MN, .RESULT, .RC, .RS, or .SIGL otherwise Msg50.1 is issued.

#### **Function name syntax**

A symbol which is the leftmost component of a function shall not end with a period, otherwise Msg51.1 is issued.

## **8.3 Syntax**

### **8.3.1 Syntax elements**

The tokens generated by the actions described in nnn form the basis for recognizing larger constructs.

```

## 8.4 Syntactic information

### 8.4.1 VAR\_SYMBOL matching

Any VAR\_SYMBOL in a *do\_ending* must be matched by the same VAR\_SYMBOL occurring at the start of an *assignment* contained in the *do\_specification* of the *do* that contains both the *do\_specification* and the *do\_ending*, as described in nnn.

If there is a VAR\_SYMBOL in a *do\_ending* for which there is no *assignment* in the corresponding *do\_specification* then message Msg10.3 is produced and no further activity is defined.

If there is a :VAR\_SYMBOL\_ in a *do\_ending* which does not match the one occurring in the *assignment* then message Msg10.2 is produced and no further activity is defined.

An *iterate* or *leave* must be contained in the *instruction\_list* of some *do* with a *do\_specification* which is *do\_repetitive*, otherwise a message (Msg28.2 or Msg28.1 respectively) is produced and no further activity is defined.

If an *iterate* or *leave* contains a VAR\_SYMBOL there must be a matching VAR\_SYMBOL in a *do\_specification*, otherwise a message (Msg28.1, Msg28.2, Msg28.3 or Msg28.4 appropriately) is produced and no further activity is defined. The matching VAR\_SYMBOL will occur at the start of an *assignment* in the *do\_specification*. The *do\_specification* will be associated with a *do* by nnn. The *iterate* or *leave* will be a single *instruction* in an *instruction\_list* associated with a *do* by nnn. These two *dos* shall be the same, or the latter nested one or more levels within the former. The number of levels is called the *nesting\_correction* and influences the semantics of the *iterate* or *leave*. It is zero if the two *dos* are the same. The *nesting\_correction* for *iterates* or *leaves* that do not contain VAR\_SYMBOL is zero.

### 8.4.2 Trace-only labels

Instances of LABEL which occur within a *grouping\_instruction* and are not in a *ncl* at the end of that *grouping\_instruction* are instances of trace-only labels.

### 8.4.3 Clauses and line numbers

The activity of tracing execution is defined in terms of clauses. A program consists of clauses, each clause ended by a semicolon special token. The semicolon may be explicit in the program or inferred. The line number of a clause is one more than the number of *EOL* events recognized before the first token of the clause was recognized.

### 8.4.4 Nested IF instructions

The syntax specification nnn allows 'IF' instructions to be nested and does not fully specify the association of an 'ELSE' keyword with an 'IF' keyword. An 'ELSE' associates with the closest prior 'IF' that it can associate with in conformance with the syntax.

### 8.4.5 Choice of messages

The specifications nnn and nnn permit two alternative messages in some circumstances. The following rules apply:

- *Msg15.1* shall be preferred to *Msg15.3* if the choice of *Msg15.3* would result in the replacement for the insertion being a blank character;
- *Msg15.2* shall be preferred to *Msg15.4* if the choice of *Msg15.4* would result in the replacement for the insertion being a blank character;
- *Msg31.3* shall be preferred to *Msg31.2* if the replacement for the insertion in the message starts with a period;
- Preference is given to the message that appears later in the list: *Msg21.1*, *Msg27.1*, *Msg25.16*, *Msg36*, *Msg38.3*, *Msg35.1*, other messages.

### 8.4.6 Creation of messages

The *message\_identifiers* in clause 6 correlate with the tails of stem *#ErrorText.*, which is initialized in nnn to identify particular messages. The action of producing an error message will replace any insertions in the message text and present the resulting text, together with information on the origin of the error, to the configuration by writing on the default error stream.

Further activity by the language processor is permitted, but not defined by this standard. The effect of an error during the writing of an error message is not defined.

#### Error message prefix

The error message selected by the message number is preceded by a prefix. The text of the prefix is *#ErrorText.0.1* except when the error is in source that execution of an interactive trace *interpret* instruction (see nnn) is processing, in which case the text is *#ErrorText.0.2*. The insert called <value> in these texts is the message number. The insert called <linenumber> is the line number of the error. The line number of the error is one more than the number of *EOL* events encountered before the error was detectable, except for messages *Msg6.1*, *Msg14*, *Msg14.1*, *Msg14.2*, *Msg14.3*, and *Msg14.4*. For *Msg6.1* it

is one more than the number of *EOL* events encountered before the line containing the unmatched `'/*'`. For the others, it is the line number of the clause containing the keyword referenced in the message text.

The insert called `<source>` is the value provided on the `API_Start` function which started processing of the program, see `nnn`.

## 8.5 Replacement of insertions

Within the text of error messages, an insertion consists of the characters `'<'`, `'>'`, and what is between those characters. There will be a word in the insertion that specifies the replacement text, with the following meaning:

- if the word is `'hex-encoding'` and the message is not *Msg23.1* then the replacement text is the value of the leftmost character which caused the source to be syntactically incorrect. The value is in hexadecimal notation;
- if the word is `'token'` then the replacement text is the part of the source program which was recognized as the detection token, or in the case of *Msg31.1* and *Msg31.2*, the token before the detection token.

The detection token is the leftmost token for which the program up to and including the token could not be parsed as the left part of a program without causing a message. If the detection token is a semicolon that was not present in the source but was supplied during recognition then the replacement is the previous token;

- if the word is `'position'` then the replacement text is a number identifying the detection character. The detection character is the leftmost character in the *hex\_string* or *binary\_string* which did not match the required syntax. The number is a count of the characters in the string which preceded the detection character, including the initial quote or apostrophe. In deciding the leftmost blank in a quoted string of radix `'X'` or `'B'` that is erroneous note that:
  - A blank as the first character of the quoted string is an error.
  - The leftmost embedded sequence of blanks can validly follow any number of non-blank characters.
  - Otherwise a blank run that follows an odd numbered sequence of non-blanks (or a number not a multiple of four in the case of radix `'B'`) is not valid.
  - If the string is invalid for a reason not described above, the leftmost blank of the rightmost sequence of blanks is the invalid blank to be referenced in the message;
- if the word is `'char'` then the replacement text is the detection character;
- if the word is `'linenumber'` then the replacement text is the line number of a clause associated with the error. The wording of the message text specifies which clause that is;
- if the word is `'keywords'` then the replacement text is a list of the keywords that the syntax would allow at the context where the error occurred. If there are two keywords they shall be separated by the four characters `' or '`. If more, the last shall be preceded by the three characters `' or '` and the others shall be followed by the two characters `','`. The keywords will be uppercased and in alphabetical order.

Replacement text is truncated to `#Limit_MessageInsert` characters if it would otherwise be longer than that, except for a keywords replacement. When an insert is both truncated and appears within quotes in the message, the three characters ' . . . ' are inserted in the message after the trailing quote.

## 8.6 Syntactic equivalence

If a `message_term` contains a '[' it is regarded as an equivalent `message_term` without a '[' , for execution. The equivalent is `term~'[]'` (`expression_list`). See `nnn`. If a `message_instruction` has the construction `message_term '=' expression` it is regarded as equivalent to a `message_term` with the same components as the `message_term` left of the '=', except that the `taken_constant` has an '=' character appended and `arguments` has the expression from the right of the '=' as an extra first argument. See `nnn`.

## Evaluation

The syntax section describes how expressions and the components of expressions are written in a program. It also describes how operators can be associated with the strings, symbols and function results which are their operands.

This evaluation section describes what values these components have in execution, or how they have no value because a condition is raised.

This section refers to the DATATYPE built-in function when checking operands, see nnn. Except for considerations of limits on the values of exponents, the test:

```
datatype(Subject) == 'NUM'
```

is equivalent to testing whether the subject matches the syntax:

```
num := [blank+] ['+' | '-' ] [blank+] number [blank+]
```

For the syntax of *number* see nnn.

When the matching subject does not include a ' - ' the value is the value of the number in the match, otherwise the value is the value of the expression (0 - number).

The test:

```
datatype(Subject , 'W')
```

is a test that the Subject matches that syntax and also has a value that is “whole”, that is has no non-zero fractional part.

When these two tests are made and the Subject matches the constraints but has an exponent that is not in the correct range of values then a condition is raised:

```
call #Raise 'SYNTAX', 20.1, word
constant
```

This possibility is implied by the uses of DATATYPE and not shown explicitly in the rest of this section nnn.

### 9.1 Variables

The values of variables are held in variable pools. The capabilities of variable pools are listed here, together with the way each function will be referenced in this definition.

The notation used here is the same as that defined in sections nnn and nnn, including the fact that the Var\_ routines may return an indicator of 'N', 'S' or 'X'.

Each possible name in a variable pool is qualified as tailed or non-tailed name; names with different qualification and the same spelling are different items in the pool. For

those `Var_` functions with a third argument this argument indicates the qualification; it is '1' when addressing tailed names or '0' when addressing non-tailed names.

Each item in a variable pool is associated with three attributes and a value. The attributes are 'dropped' or 'not-dropped', 'exposed' or 'not-exposed' and 'implicit' or 'not-implicit'.

A variable pool is associated with a reference denoted by the first argument, with name `Pool`. The value of `Pool` may alter during execution. The same name, in conjunction with different values of `Pool`, can correspond to different values.

### 9.1.1 `Var_Empty`

`Var_Empty(Pool)`

The function sets the variable pool associated with the specified reference to the state where every name is associated with attributes 'dropped', 'implicit' and 'not-exposed'.

### 9.1.2 `Var_Set`

`Var_Set(Pool, Name, '0', Value)`

The function operates on the variable pool with the specified reference. The name is a non-tailed name. If the specified name has the 'exposed' attribute then `Var_Set` operates on the variable pool referenced by `#Upper` in this pool and this rule is applied to that pool. When the pool with attribute 'not-exposed' for this name is determined the specified value is associated with the specified name. It also associates the attributes 'not-dropped' and 'not-implicit'. If that attribute was previously 'not-dropped' then the indicator returned is 'R'. The name is a stem if it contains just one period, as its rightmost character. When the name is a stem `Var_Set(Pool, TailedName, '1', Value)` is executed for all possible valid tailed names which have `Name` as their stem, and then those tailed-names are given the attribute 'implicit'.

`Var_Set(Pool, Name, '1', Value)`

The function operates on the variable pool with the specified reference. The name is a tailed name. The left part of the name, up to and including the first period, is the stem. The stem is a non-tailed name. If the specified stem has the 'exposed' attribute then `Var_Set` operates on the variable pool referenced by `#Upper` in this pool and this rule is applied to that pool. When the pool with attribute 'not-exposed' for the stem is determined the name is considered in that pool. If the name has the 'exposed' attribute then the variable pool referenced by `#Upper` in the pool is considered and this rule applied to that pool. When the pool with attribute 'not-exposed' is determined the specified value is associated with the specified name. It also associates the attributes 'not-dropped' and 'not-implicit'. If that attribute was previously 'not-dropped' then the indicator returned is 'R'.

### 9.1.3 `Var_Value`

`Var_Value(Pool, Name, '0')`

The function operates on the variable pool with the specified reference. The name is a non-tailed name. If the specified name has the 'exposed' attribute then `Var_Value`

operates on the variable pool referenced by #Upper in this pool and this rule is applied to that pool. When the pool with attribute 'not-exposed' for this name is determined the indicator returned is 'D' if the name has 'dropped' associated, 'N' otherwise.

In the former case #Outcome is set equal to Name, in the latter case #Outcome is set to the value most recently associated with the name by Var\_Set.

`Var_Value(Pool, Name, '1')`

The function operates on the variable pool with the specified reference. The name is a tailed name. The left part of the name, up to and including the first period, is the stem. The stem is a non-tailed name. If the specified stem has the 'exposed' attribute then Var\_Value operates on the variable pool referenced by #Upper in this pool and this rule is applied to that pool. When the pool with attribute 'not-exposed' for the stem is determined the name is considered in that pool. If the name has the 'exposed' attribute then the variable pool referenced by #Upper in the pool is considered and this rule applied to that pool. When the pool with attribute 'not-exposed' is determined the indicator returned is 'D' if the name has 'dropped' associated, 'N' otherwise. In the former case #Outcome is set equal to Name, in the latter case #Outcome is set to the value most recently associated with the name by Var\_Set.

#### **9.1.4 Var\_Drop**

`Var_Drop(Pool, Name, '0')`

The function operates on the variable pool with the specified reference. The name is a non-tailed name. If the specified name has the 'exposed' attribute then Var\_Drop operates on the variable pool referenced by #Upper in this pool and this rule is applied to that pool. When the pool with attribute 'not-exposed' for this name is determined the attribute 'dropped' is associated with the specified name. Also, when the name is a stem, Var\_Drop(Pool, TailedName, '1') is executed for all possible valid tailed names which have Name as a stem.

`Var_Drop(Pool, Name, '1')`

The function operates on the variable pool with the specified reference. The name is a tailed name. The left part of the name, up to and including the first period, is the stem. The stem is a non-tailed name. If the specified stem has the 'exposed' attribute then Var\_Drop operates on the variable pool referenced by #Upper in this pool and this rule is applied to that pool. When the pool with attribute 'not-exposed' for the stem is determined the name is considered in that pool. If the name has the 'exposed' attribute then the variable pool referenced by #Upper in the pool is considered and this rule applied to that pool. When the pool with attribute 'not-exposed' is determined the attribute 'dropped' is associated with the specified name.

#### **9.1.5 Var\_Expose**

`Var_Expose (Pool, Name, '0')`

The function operates on the variable pool with the specified reference. The name is a non-tailed name. The attribute 'exposed' is associated with the specified name. Also, when the name is a stem, Var\_Expose(Pool, TailedName, '1') is executed for all possible valid tailed names which have Name as a stem.

Var\_Expose (Pool, Name, '1')

The function operates on the variable pool with the specified reference. The name is a tailed name. The attribute 'exposed' is associated with the specified name.

### 9.1.6 Var\_Reset

Var\_ Reset (Pool)

The function operates on the variable pool with the specified reference. It establishes the effect of subsequent API\_Next and API\_NextVariable functions (see sections nnn and nnn). A Var\_Reset is implied by any API\_ operation other than API\_Next and API\_NextVariable.

## 9.2 Symbols

For the syntax of a symbol see nnn.

The value of a symbol which is a *NUMBER* or a *CONST\_SYMBOL* which is not a reserved symbol is the content of the appropriate token.

The value of a *VAR\_SYMBOL* which is “taken as a constant” is the *VAR\_SYMBOL* itself, otherwise the *\_VAR\_SYMBOL*: identifies a variable and its value may vary during execution.

Accessing the value of a symbol which is not “taken as a constant” shall result in trace output, see nnn:

```
if #Tracing.#Level == 'I' then call #Trace Tag
```

where Tag is '>L>' unless the symbol is a *VAR\_SYMBOL* which, when used as an argument to Var\_Value, does not yield an indicator 'D'. In that case, the Tag is '>V>'.

## 9.3 Value of a variable

If *VAR\_SYMBOL* does not contain a period, or contains only one period as its last character, the value of the variable is the value associated with *VAR\_SYMBOL* in the variable pool, that is #Outcome after Var\_Value(Pool, VAR\_SYMBOL, '0').

If the indicator is 'D', indicating the variable has the ‘dropped’ attribute, the NOVALUE condition is raised; see nnn and nnn for exceptions to this.

```
#Response = Var Value(Pool, VAR SYMBOL, '0')
if left(#Response,1) == 'D' then
  call #Raise 'NOVALUE', VAR_SYMBOL, ''
```

If *VAR\_SYMBOL* contains a period which is not its last character, the value of the variable is the value associated with the derived name.

### 9.3.1 Derived names

A derived name is derived from a *VAR\_SYMBOL* as follows:

```

VAR SYMBOL := Stem Tail
Stem := PlainSymbol '.'
Tail := (PlainSymbol | '.' [PlainSymbol]) ['.' [PlainSymbol]]+
PlainSymbol := (general_letter | digit)+

```

The derived name is the concatenation of:

- the *Stem*, without further evaluation;
- the *Tail*, with the *PlainSymbols* replaced by the values of the symbols. The value of a *PlainSymbol* which does not start with a digit is #Outcome after

```
Var_Value (Pool, PlainSymbol, '0')
```

These values are obtained without raising the NOVALUE condition.

If the indicator from the Var\_Value was not 'D' then: if #Tracing.#Level == 'I' then call #Trace '>C>'

The value associated with a derived name is obtained from the variable pool, that is #Outcome after: Var\_Value(Pool,Derived Name,'I')

If the indicator is 'D', indicating the variable has the 'dropped' attribute, the NOVALUE condition is raised; see nnn for an exception.

### 9.3.2 Value of a reserved symbol

The value of a reserved symbol is the value of a variable with the corresponding name in the reserved pool, see nnn.

## 9.4 Expressions and operators

Add a load of string coercions. Equality can operate on non-strings. What if one operand non-string?

### 9.4.1 The value of a term

See nnn for the syntax of a term.

The value of a STRING is the content of the token; see nnn.

The value of a function is the value it returns, see nnn.

If a term is a symbol or STRING then the value of the term is the value of that symbol or STRING.

If a term contains an expr\_alias the value of the term is the value of the expr\_alias, see nnn.

### 9.4.2 The value of a prefix\_expression

If the prefix\_expression is a term then the value of the prefix\_expression is the value of the term, otherwise let rhs be the value of the prefix\_expression within it\_\_ see nnn

If the `prefix_expression` has the form `'+' prefix_expression` then a check is made: if `datatype(rhs)=='NUM'` then call `#Raise 'SYNTAX',41.3, rhs, '+'`

and the value is the value of  $(0 + \text{rhs})$ .

If the `prefix_expression` has the form `'-' prefix_expression` then a check is made: if `datatype(rhs)=='NUM'` then call `#Raise 'SYNTAX',41.3, rhs, '-'`

and the value is the value of  $(0 - \text{rhs})$ .

If a `prefix_expression` has the form `not prefix_expression` then if `rhs == '0'` then if `rhs == '1'` then call `#Raise 'SYNTAX', 34.6, not, rhs`

See `nnn` for the value of the third argument to that `#Raise`. If the value of `rhs` is `'0'` then the value of the `prefix_expression` value is `'1'`, otherwise it is `'0'`.

If the `prefix_expression` is not a term then: if `#Tracing.#Level == 'T'` then call `#Trace '>P>'`

### 9.4.3 The value of a power\_expression

See `nnn` for the syntax of a `power_expression`.

If the `power_expression` is a `prefix_expression` then the value of the `power_expression` is the value of the `prefix_expression`.

Otherwise, let `lhs` be the value of `power_expression` within it, and `rhs` be the value of `prefix_expression` within it.

```
if datatype(lhs)\=='NUM' then call #Raise 'SYNTAX',41.1, lhs, '**'
```

```
if \datatype(rhs,'W') then call #Raise 'SYNTAX',26.1, rhs, '**'
```

`power_expression` is

`ArithOp(lhs,'**',rhs)`

If the `power_expression` is not a `prefix_expression` then: if `#Tracing.#Level == 'T'` then call `#Trace '>0O>'`

### 9.4.4 The value of a multiplication

See `nnn` for the syntax of a multiplication. If the multiplication is a `power_expression` then the value of the multiplication is the value of the `power_expression`. Otherwise, let `lhs` be the value of multiplication within it, and `rns` be the value of `power_expression` within it. if `datatype(lhs)=='NUM'` then call `#Raise 'SYNTAX',41.1, lhs, multiplicative operation` if `datatype(rhs)=='NUM'` then call `#Raise 'SYNTAX',41.2, rhs, multiplicative operation`

The value of the multiplication is `ArithOp(lhs, multiplicative operation, rhs)`

If the multiplication is not a `power_expression` then:

if `#Tracing.#Level == 'T'` then call `#Trace '>0O>'`

### 9.4.5 The value of an addition

See `nnn` for the syntax of addition.

If the addition is a multiplication then the value of the addition is the value of the multiplication. Otherwise, let lhs be the value of addition within it, and rhs be the value of the multiplication within it. Let

operation be the additive\_operator. if datatype(lhs)=='NUM' then

call #Raise 'SYNTAX', 41.1, lhs, operation if datatype(rhs)=='NUM' then

call #Raise 'SYNTAX', 41.2, rhs, operation

If either of rhs or lhs is not an integer then the value of the addition is ArithOp(lhs, operation, rhs) Otherwise if the operation is '+' and the length of the integer lhs+rhs is not greater than #Digits.#Level

then the value of addition is lhs+rhs

Otherwise if the operation is '-' and the length of the integer lhs-rhs is not greater than #Digits.#Level then

the value of addition is lhs-rhs

Otherwise the value of the addition is ArithOp(lhs, operation, rhs)

If the addition is not a multiplication then: if #Tracing.#Level == 'T' then call #Trace '>0O>'

#### 9.4.6 The value of a concatenation

See nnn for the syntax of a concatenation. If the concatenation is an addition then the value of the concatenation is the value of the addition. Otherwise, let lhs be the value of concatenation within it, and rhs be the value of the additive\_expression within it. If the concatenation contains '|' then the value of the concatenation will have the following characteristics:

- Config\_Length(Value) will be equal to Config\_Length(lhs)+Config\_Length(rhs).
- #Outcome will be 'equal' after each of:
- Config\_Compare(Config\_Subsir(lhs,n)),Config\_Substr(Value,n)) for values of n not less than 1 and not more than Config\_Length(lhs);
- Config\_Compare(Config\_Subsir(rhs,n),Config\_Substr(Value,Config\_Length(lhs)+n)) for values of n not less than 1 and not more than Config\_Length(rhs). Otherwise the value of the concatenation will have the following characteristics:
- Config\_Length(Value) will be equal to Config\_Length(lhs)+1+Config\_Length(rhs).
- #Outcome will be 'equal' after each of:
- Config\_Compare(Config\_Subsir(lhs,n)),Config\_Substr(Value,n)) for values of n not less than 1 and not more than Config\_Length(lhs);
- Config\_Compare(' ',Config\_Substr(Value,Config\_Length(lhs))+1));
- Config\_Compare(Config\_Substr(rhs,n),Config\_Substr(Value,Config\_Length(lhs)+1+n)) for values of n not less than 1 and not more than Config\_Length(rhs).

If the concatenation is not an addition then: if #Tracing.#Level == 'T' then call #Trace '>0O>'

### 9.4.7 The value of a comparison

See nnn for the syntax of a comparison.

If the comparison is a concatenation then the value of the comparison is the value of the concatenation. Otherwise, let lhs be the value of the comparison within it, and rhs be the value of the concatenation within it.

If the comparison has a comparison\_operator that is a strict\_compare then the variable #Test is set as follows:

#Test is set to 'E'. Let Length be the smaller of Config\_Length(lhs) and Config\_Length(rhs). For values of n greater than 0 and not greater than Length, if any, in ascending order, #Test is set to the uppercased first character of #Outcome after:

Config\_Compare(Config\_Subsir(lhs),Config\_Subsir(rhs)).

If at any stage this sets #Test to a value other than 'E' then the setting of #Test is complete. Otherwise, if Config\_Length(lhs) is greater than Config\_Length(rhs) then #Test is set to 'G' or if Config\_Length(lhs) is less than Config\_Length(rhs) then #Test is set to 'L'.

If the comparison has a comparison\_operator that is a normal\_compare then the variable #Test is set as follows:

```
if datatype(lhs)\== 'NUM' | datatype(rhs)\== 'NUM' then do
/* Non-numeric non-strict comparison */
lhs=strip(lhs, 'B', ' ') /* ExtraBlanks not stripped */
rhs=strip(rhs, 'B', ' ')

if length(lhs)>length(rhs) then rhs=left (rhs, length (lhs) )
else lhs=left (lhs, length (rhs) )
if lhs>>rhs then #Test='G'
else if lhs<<rhs then #Test='L'
else #Test='E'

end
else do /* Numeric comparison */
if left(-lhs,1) == '-' & left(+rhs,1) \== '-' then #Test='G!'
else if left(-rhs,1) == '-' & left(+lhs,1) \== '-' then #Test='L'
else do
Difference=lhs - rhs /* Will never raise an arithmetic condition. */
if Difference > 0 then #Test='G'
else if Difference < 0 then #Test='L'
else #Test='E'
end
end
```

The value of #Test, in conjunction with the operator in the comparison, determines the value of the comparison. The value of the comparison is '1' if - #Test is 'E' and the operator is one of '=' '==', '>=', '<=', '>', '<', 'p>=', '«=», »', or «)

- #Test is 'G' and the operator is one of '>', '>=', '<', '=', '<>', '><', Nes'', »! 'p>', or «)
- #Test is 'L' and the operator is one of '<', '<=', '>', '=', '<>', '><', '==', «', \*«=, or »'. In all other cases the value of the comparison is '0'.

If the comparison is not a concatenation then: if #Tracing.#Level == 'T' then call #Trace '>0O>'

#### 9.4.8 The value of an and\_expression

See nnn for the syntax of an and\_expression.

If the and\_expression is a comparison then the value of the and\_expression is the value of the comparison.

Otherwise, let lhs be the value of the and\_expression within it, and rhs be the value of the comparison within it.

if lhs == '0' then if lhs == '1' then call #Raise 'SYNTAX',34.5,lhs,'&'

if rhs == '0' then if rhs == '1' then call #Raise 'SYNTAX',34.6,rhs,'&'

Value='0'

if lhs == '1' then if rhs == '1' then Value='1'

If the and\_expression is not a comparison then:

if #Tracing.#Level == 'T' then call #Trace '>0O>'

#### 9.4.9 The value of an expression

See nnn for the syntax of an expression.

The value of an expression, or an expr, is the value of the expr\_alias within it.

If the expr\_alias is an and\_expression then the value of the expr\_alias is the value of the and\_expression. Otherwise, let lhs be the value of the expr\_alias within it, and rhs be the value of the and\_expression

within it. if lhs == '0' then if lhs == '1' then

call #Raise 'SYNTAX',34.5,lhs,or operator if rhs == '0' then if rhs == '1' then

call #Raise 'SYNTAX',34.6,rhs,or operator Value='1' if lhs == '0' then if rhs == '0' then Value='0' If the or\_operator is '&&' then if lhs == '1' then if rhs == '1' then Value='0' If the expr\_alias is not an and\_expression then: if #Tracing.#Level == 'T' then call #Trace '>0O>'

The value of an expression or expr shall be traced when #Tracing.#Level is 'R'. The tag is '>=>' when

the value is used by an assignment and '>>>' when it is not. if #Tracing.#Level == 'R' then call #Trace Tag

#### 9.4.10 Arithmetic operations

The user of this standard is assumed to know the results of the binary operators '+' and '-' applied to signed or unsigned integers.

The code of ArithOpp itself is assumed to operate under a sufficiently high setting of numeric digits to avoid exponential notation.

ArithOpp:

```
arg Number1, Operator, Number2
/* The Operator will be applied to Number1 and Number2 under the
   numeric
```

```

settings #Digits.#Level, #Form.#Level, #Fuzz.#Level */

/* The result is the result of the operation, or the raising of a '
  SYNTAX' or
  'LOSTDIGITS' condition. */

/* Variables with digit 1 in their names refer to the first argument
  of the
  operation. Variables with digit 2 refer to the second argument.
  Variables
  with digit 3 refer to the result. */

/* The quotations and page numbers are from the first reference in
  Annex C of this standard. */

/* The operands are prepared first. (Page 130) Function Prepare does
  this,
  separating sign, mantissa and exponent. */

v = Prepare (Number1, #Digits.#Level)
parse var v Sign1 Mantissa1 Exponent1

v = Prepare (Number2, #Digits.#Level)
parse var v Sign2 Mantissa2 Exponent2

/* The calculation depends on the operator. The routines set Sign3
  Mantissa3 and Exponent3. */

Comparator = ''

select
when Operator == '*' then call Multiply

when Operator
when Operator

## 9.5 Functions

### 9.5.1 Invocation

Invocation occurs when a *function* or a *message\_term* or a *call* is evaluated. Invocation of a function may result in a value, in which case:

```
if #Tracing.#Level == 'I' then call #Trace '>F>'
```

Invocation of a *message\_term* may result in a value, in which case:

```
if #Tracing.#Level == 'I' then call #Trace '>M>'
```

### 9.5.2 Evaluation of arguments

The argument positions are the positions in the *expression\_list* where syntactically an *expression* occurs or could have occurred. Let ArgNumber be the number of an argument position, counting from 1 at the left; the range of ArgNumber is all whole numbers greater than zero.

For each value of ArgNumber, #ArgExists.#NewLevel.ArgNumber is set '1' if there is an expression present, '0' if not.

From the left, if #ArgExists.#NewLevel.ArgNumber is '1' then #Arg.#NewLevel.ArgNumber is set to the value of the corresponding expression. If #ArgExists.#NewLevel.ArgNumber is '0' then #Arg.#NewLevel.ArgNumber is set to the null string.

#ArgExists.#NewLevel.0 is set to the largest ArgNumber for which #ArgExists.#NewLevel.ArgNumber is '1', or to zero if there is no such value of ArgNumber.

### 9.5.3 The value of a label

The value of a *LABEL*, or of the *taken\_constant* in the function or *call\_instruction*, is taken as a constant, see nnn. If the *taken\_constant* is not a *string\_literal* it is a reference to the first *LABEL* in the program which has the same value. The comparison is made with the '=' operator.

If there is such a matching label and the label is trace-only (see nnn) then a condition is raised:

```
call #Raise 'SYNTAX', 20.1, word  
constant
```

If there is such a matching label, and the label is not trace-only, execution continues at the label with routine initialization (see nnn). This is execution of an internal routine.

If there is no such matching label, or if the *taken\_constant* is a *string\_literal*, further comparisons are made.

If the value of the *taken\_constant* matches the name of some built-in function then that built-in function is invoked. The names of the built-in functions are defined in section nnn and are in uppercase.

If the value does not match any built-in function name, Config\_ExternalRoutine is used to invoke an external routine.

Whenever a matching label is found, the variables SIGL and .SIGL are assigned the value of the line number of the clause which caused the search for the label. In the case of an invocation resulting from a condition occurring that shall be the clause in which the condition occurred.

```
Var_Set(#Pool, 'SIGL', '0', #LineNumber)
var_Set(0, '.SIGL', '0', #LineNumber)
```

The name used in the invocation is held in #Name.#Level for possible use in an error message from the RETURN clause, see nnn

#### 9.5.4 The value of a function

A built-in function completes when it returns from the activity defined in section nnn. The value of a built-in function is defined in section nnn.

An internal routine completes when #Level returns to the value it had when the routine was invoked. The value of the internal function is the value of the *expression* on the *return* which completed the routine. The value of an external function is determined by Config\_ExternalRoutine.

#### 9.5.5 The value of a method

A built-in method completes when it returns from the activity defined in section n. The value of a built-in method is defined in section n.

An internal method completes when #Level returns to the value it had when the routine was invoked. The value of the internal method is the value of the *expression* on the *return* which completed the method. The value of an external method is determined by Config\_ExternalMethod.

#### 9.5.6 The value of a message term

See nnn for the syntax of a *message\_term*. The value of the *term* within a *message\_term* is called the receiver.

The receiver and any arguments of the term are evaluated, in left to

```
r = #evaluate(message_term, term)
```

If the message term contains '~~' the value of the message term is the receiver.

*Any effect on .Result?*

Otherwise the value of a *message\_term* is the value of the method it invokes. The method invoked is determined by the receiver and the *taken\_constant* and *symbol*.

```
t = #Instance(message term, taken constant)
```

If there is a *symbol*, it is subject to a constraints.

```
if #contains(message term, symbol) then do
  if r <> #Self then
    call #Raise 'SYNTAX', nn.n
```

```

        /* 00I: "Message search overrides can only be used from methods
           of the target
object." */

```

The search will progress from the object to its class and superclasses.

```

/* This is going to be circular because it describes the message
lookup
algorithm and also uses messages. However for the messages in this
code
the message names are chosen to be unique to a method so there is no
need
to use this algorithm in deciding which method is intended. */

/* message term ::= receiver '~' taken constant ':' VAR_SYMBOL
arguments */

```

```

/* This code reflects 00I - the arguments on the message don't affect
the method choice. */

```

```

### 9.5.7 Use of Config\_ExternalRoutine

The values of the arguments to the use of Config\_ExternalRoutine, in order, are:

The argument How is 'SUBROUTINE' if the invocation is from a *call*, 'FUNCTION' if the invocation is from a *function*.

The argument NameType is '1' if the *taken\_constant* is a *string\_literal*, '0' otherwise.

The argument Name is the value of the *taken\_constant*.

The argument Environment is the value of this argument on the API\_Start which started this execution.

The argument Arguments is the #Arg. and #ArgExists. data.

The argument Streams is the value of this argument on the API\_Start which started this execution.

The argument Traps is the value of this argument on the API\_Start which started this execution.

Var\_Reset is invoked and #API\_Enabled set to '1' before use of Config\_ExternalRoutine. #API\_Enabled is set to '0' after.

The response from Config\_ExternalRoutine is processed. If no conditions are (implicitly) raised, #Outcome is the value of the function.

## Directives

The syntax constructs which are introduced by the optional ‘::’ token are known as directives.

### 10.1 Notation

Notation functions are functions which are not directly accessible as functions in a program but are used in this standard as a notation for defining semantics.

Some notation functions allow reference to syntax constructs defined in nnn. Which instance of the syntax construct in the program is being referred to is implied; it is the one for which the semantics are being specified.

The BNF\_primary referenced may be directly in the production or in some component referenced in the *production*, recursively. The components are considered in left to right order.

#Contains(Identifier, BNF primary)

where:

- Identifier is an *identifier* in a *production* (see nnn) defined in nnn.
- BNF\_primary is a *bnf\_primary* (see nnn) in a *production* defined in nnn.

Return '1' if the *production* identified by *Identifier* contained a *bnf\_primary* identified by BNF\_primary, otherwise return '0'.

#Instance(Identifier, BNF primary)

where:

- Identifier is an *identifier* in a *production* defined in nnn.
- BNF\_primary is a *bnf\_primary* in a *production* defined in nnn.

Returns the content of the particular instance of the BNF\_primary. If the BNF\_primary is a VAR\_SYMBOL this is referred to as the symbol “taken as a constant.”

#Evaluate(Identifier, BNF primary)

where:

- Identifier is an *identifier* in a *production* defined in nnn.
- BNF\_primary is a *bnf\_primary* in a *production* defined in nnn.

Return the value of the BNF\_primary in the *production* identified by Identifier.

#Execute(Identifier, BNF primary)

where:

- Identifier is an *identifier* in a *production* defined in nnn.
- BNF\_primary is a *bnf\_primary* in a *production* defined in nnn.

Perform the instructions identified by the BNF\_primary in the *production* identified by Identifier.

#Parses(Value, BNF primary)

where:

- Value is a string
- BNF\_primary is a *bnf\_primary* in a *production* defined in nnn.

Return '1' if Value matches the definition of the BNF\_primary, by the rules of clause 6, '0' otherwise.

#Clause(Label)

where:

- Label is a label in code used by this standard to describe processing.

Return an identification of that label. The value of this identification is used only by the #Goto notation function.

#Goto(Value)

where:

- Value identifies a label in code used by this standard to describe processing.

The description of processing continues at the identified label.

#Retry( )

/

This notation is used in the description of interactive tracing to specify re-execution of the clause just previously executed. It has the effect of transferring execution to the beginning of that clause, with state variable #Loop set to the value it had when that clause was previously executed.

## 10.2 Initializing

*Some of the initializing, now grouped in classic section 8.2.1 will have to come here so that we have picked up anything from the START\_API that needs to be passed on to the execution of REQUIRES subject. We will be using some operations that are forward reference to what was section nnn.*

### 10.2.1 Program initialization and message texts

Processing of a program begins when `API_Start` is executed. A pool becomes current for the reserved variables.

```
call Config ObjectNew
#ReservedPool = #Outcome
#Pool = #ReservedPool
```

*Is it correct to make the reserved variables and the builtin objects in the same pool?*

Some of the values which affect processing of the program are parameters of `API_Start`: `#HowInvoked` is set to 'COMMAND', 'FUNCTION' or 'SUBROUTINE' according to the first parameter of `API_Start`.

`#Source` is set to the value of the second parameter of `API_Start`.

The third parameter of `API_Start` is used to determine the initial active environment.

The fourth parameter of `API_Start` is used to determine the arguments. For each argument position `#ArgExists.1.ArgNumber` is set '1' if there is an argument present, '0' if not. `ArgNumber` is the number of the argument position, counting from 1. If `#ArgExists.1.ArgNumber` is '1' then `#Arg.1.ArgNumber` is set to the value of the corresponding argument. If `#ArgExists.1.ArgNumber` is '0' then `#Arg.1.Arg` is set to the null string. `#ArgExists.1.0` is set to the largest `n` for which `#ArgExists.1.n` is '1', or to zero if there is no such value of `n`.

Some of the values which affect processing of the program are provided by the configuration:

```
call Config OtherBlankCharacters
#AllBlanks<Index "#AllBlanks" # "" > = ' '#Outcome /* "Real" blank
    concatenated with
others */
#Bif Digits. = 9
call Config Constants
.true = '1'
.false = '0'
```

model are only distinguished by the values within their pool so we can construct the builtin classes incomplete and then complete them with directives.\_

\_Can we initialize the methods of `.nil` by directives?\_

```
call Config_ObjectNew
.List = #Outcome
call var_set .List, #IsClass, '0', '1'
call var_set .List, #ID, '0', 'List'
```

Some of the state variables set by this call are limits, and appear in the text of error messages. The relation between message numbers and message text is defined by the following list, where the message number appears immediately before an '=' and the message text follows in quotes.

```
#ErrorText.    = ''
#ErrorText.0.1 = 'Error <value> running <source>, line <linenumber>:'
#ErrorText.0.2 = 'Error <value> in interactive trace: '
#ErrorText.0.3 = 'Interactive trace. "Trace Off" to end debug. ',
```

```

If the activity defined by clause 6 does not produce any error message, execution of the program continues.

**call** Config NoSource

If Config\_NoSource has set #NoSource to '0' the lines of source processed by clause 6 are copied to #SourceLine. , with #SourceLine.0 being a count of the lines and #SourceLine.n for n=1 to #SourceLine.0 being the source lines in order.

If Config\_NoSource has set #NoSource to '1' then #SourceLine.0 is set to 0.

The following state variables affect tracing:

```

#InhibitPauses = 0
#InhibitTrace = 0
#AtPause = 0 /* Off until interactive input being received. */
#Trace QueryPrior = 'No'

```

An initial variable pool is established:

```

call Config ObjectNew
#Pool = #Outcome
#Pool1 = #Pool
call Var_Empty #Pool
call Var_Reset #Pool
#Level = 1 /* Level of invocation */
#NewLevel = 2
#IsFunction.#Level = (#HowInvoked == 'FUNCTION')

```

For this first level, there is no previous level from which values are inherited. The relevant fields are initialized.

```

#Digits.#Level = 9 /* Numeric Digits */
#Form.#Level = 'SCIENTIFIC' /* Numeric Form */
#Fuzz.#Level = 0 /* Numeric Fuzz */

```

```
#StartTime.#Level = '' /* Elapsed time boundary */
#LineNumber = ''
#Tracing.#Level = 'N'
#Interactive.#Level = '0'
```

An environment is provided by the API\_Start to become the initial active environment to which commands will be addressed. The alternate environment is made the same:

```
/* Call the environments ACTIVE, ALTERNATE, TRANSIENT where these are
never-initialized state variables.
Similarly call the redirections I 0 and E */
call EnvAssign ALTERNATE, #Level, ACTIVE, #Level
```

Conditions are initially disabled:

```
#Enabling.SYNTAX.#Level = 'OFF'
#Enabling.HALT.#Level = 'OFF'
#Enabling.ERROR.#Level = 'OFF'
#Enabling.FAILURE.#Level = 'OFF'
#Enabling.NOTREADY.#Level = 'OFF'
#Enabling.NOVALUE.#Level = 'OFF'
#Enabling.LOSTDIGITS.#Level = 'OFF'
#PendingNow.HALT.#Level = 0
#PendingNow.ERROR.#Level = 0
#PendingNow.FAILURE.#Level = 0
#PendingNow.NOTREADY.#Level = 0
/* The following field corresponds to the results from the CONDITION
built-in
function. */
#Condition.#Level = ''
```

The opportunity is provided for a trap to initialize the pool.

```
#API Enabled = '1'
call Var_Reset #Pool
call Config Initialization
#API Enabled = '0'
```

## 10.3 REQUIRES

For each requires in order of appearance:

*A use of Start\_API with #instance(requires, taken\_constant). Msg40.1 or a new if completion 'E'. Add Provides to an ordered collection. Not cyclic because .LIST can be defined without defining REQUIRES but a fairly profound forward reference.*

## 10.4 CLASS

For each class in order of appearance:

```
#ClassName = #Instance(class, taken constant)
call var_value #ReservedPool, '#CLASSES.'ClassName, '1'
if #Indicator == 'D' then do
```

```

call Config ObjectNew
#Class = #Outcome
call var_set #ReservedPool, '#CLASSES.'#ClassName, '1', #Class
end
else call #Raise 'SYNTAX', nn.nn, #ClassName

```

*New instance of CLASS class added to list. Msg “Duplicate ::CLASS directive instruction”(?)*

**## METHOD**

For each method in order of appearance:

```

call Config ObjectNew
#Pool = #Outcome
call Config ObjectSource (#Pool)
#MethodName = #Instance(method, taken_constant)
call var_value #Class, '#METHODS.'#MethodName, '1'
if #Indicator == 'D' then
    call var set #Class, '#METHODS.'#MethodName, '1', #Pool
else call #Raise 'SYNTAX', nn.nn, #MethodName, #ClassName

```

*GUARDED & public is default. if #contains(method, 'PRIVATE') then m~setprivate; if*

*#contains(method, 'UNGUARDED') then m~setunguarded*

*Why is there a keyword for GUARDED but not for PUBLIC here?*

*Does CLASS option mean ENHANCE with Class class methods?*

*#CurrentClass~class(#instance(method, taken\_constant), m)*

*For ATTRIBUTE, should we actually construct source for two methods? ATTRIBUTE case needs test of null body. OOI doesn't have source (because it actually traps UNKNOWN?).*

*For EXTERNAL test for null body. Simon Nash doc says “Accessibility to external methods ... is implementation-defined”. Left like that it doesn't even tell us about search order. We will need a Config\_ExternalClass to import the public names of the class.*

## 10.5 ROUTINE

For each routine in order of appearance:

*Add name (with duplicate check) to list for this file.*

*Extra step needed in the invocation search order. Although this is nominally EXTERNAL we presumably won't use the external call mechanism. (Except perhaps when the routine was made available by a REQUIRES; in that case the PARSE SOURCE answer has to change.) I have the builtins-defined-by-directives elsewhere; it would make sense if they wound up about here.*

## Instructions

---

This clause describes the execution of instructions, and how the sequence of execution can vary from the normal execution in order of appearance in the program.

Execution of the program begins with its first clause.

*If we left Routine initialization to here we can leave method initialization.*

### 11.1 Method initialization

There is a pool for local variables.

```
call Config_ObjectNew
#Pool = #Outcome
```

*Set self and super*

### 11.2 Routine initialization

If the routine is invoked as a function, #IsFunction.#NewLevel shall be set to '1', otherwise to '0'; this affects the processing of a subsequent RETURN instruction.

```
#AllowProcedure.#NewLevel = '1'
```

Many of the initial values for a new invocation are inherited from the caller's values.

```
#Digits.#NewLevel = #Digits.#Level
#Form.#NewLevel = #Form.#Level
#Fuzz.#NewLevel = #Fuzz.#Level
```

```
#StartTime.#NewLevel = #StartTime.#Level
```

```
#Tracing.#NewLevel = #Tracing.#Level
#Interactive.#NewLevel = #Interactive.#Level
```

```
call EnvAssign ACTIVE, #NewLevel, ACTIVE, #Level
call EnvAssign ALTERNATE, #NewLevel, ALTERNATE, #Level
```

```
do t=1 to 7
  Condition = word('SYNTAX HALT ERROR FAILURE NOTREADY NOVALUE
    LOSTDIGITS',t)
  #Enabling.Condition.#NewLevel = #Enabling.Condition.#Level
  #Instruction.Condition.#NewLevel = #Instruction.Condition.#Level
  #TrapName.Condition.#NewLevel = #TrapName.Condition.#Level
  #EventLevel.Condition.#NewLevel = #EventLevel.Condition.#Level
end t
```

If this invocation is not caused by a condition occurring, see nnn, the state variables for the CONDITION built-in function are copied.

```
#Condition.#NewLevel = #Condition.#Level
#ConditionDescription.#NewLevel = #ConditionDescription.#Level
#ConditionExtra.#NewLevel = #ConditionExtra.#Level
#ConditionInstruction.#NewLevel = #ConditionInstruction.#Level
```

Execution of the initialized routine continues at the new level of invocation.

```
#Level = #Level-1
#NewLevel = #Level+1
1
```

### 11.3 Clause initialization

The clause is traced before execution:

```
if pos(#Tracing.#Level, 'AIR') > 0 then call #TraceSource
```

The time of the first use of DATE or TIME will be retained throughout the clause.

```
#ClauseTime.#Level = ''
```

The state variable #LineNumber is set to the line number of the clause, see nnn.

A clause other than a null clause or label or procedure instruction sets:

```
#AllowProcedure.#Level = '0' /* See message 17.1 */
```

### 11.4 Clause termination

```
if #InhibitTrace > 0 then #InhibitTrace = #InhibitTrace - 1
```

Polling for a HALT condition occurs:

```
#Response = Config_Halt_Query ()
if #Outcome == 'Yes' then do
  call Config_Halt_Reset
  call #Raise 'HALT', substr(#Response,2) /* May return */
end
```

At the end of each clause there is a check for conditions which occurred and were delayed. It is acted on if this is the clause in which the condition arose.

```
do t=1 to 4
  #Condition=WORD('HALT FAILURE ERROR NOTREADY',t)
  /* HALT can be established during HALT handling. */
  do while #PendingNow.#Condition.#Level
    #PendingNow.#Condition.#Level = '0'
    call #Raise
  end
end
```

be turned on via the configuration. Only a change in the setting is significant.

```

call Config_Trace_Query
if #AtPause = 0 & #Outcome == 'Yes' & #Trace QueryPrior == 'No' then
  do
    /* External request for Trace '?R!' */
    #Interactive.#Level = '1'
    #Tracing.#Level = 'R'
  end
#TraceQueryPrior = #Outcome

```

*Tracing just not the same with NetRexx.*

When tracing interactively, pauses occur after the execution of each clause except for CALL, DO the second or subsequent time through the loop, END, ELSE, EXIT, ITERATE, LEAVE, OTHERWISE, RETURN, SIGNAL, THEN and null clauses.

If the character '=' is entered in response to a pause, the prior clause is re-executed.

Anything else entered will be treated as a string of one or more clauses and executed by the language processor. The same rules apply to the contents of the string executed by interactive trace as do for strings executed by the INTERPRET instruction. If the execution of the string generates a syntax error, the standard message is displayed but no condition is raised. All condition traps are disabled during execution of the string. During execution of the string, no tracing takes place other than error or failure return codes from commands. The special variable RC is not set by commands executed within the string, nor is .RC.

If a TRACE instruction is executed within the string, the language processor immediately alters the trace setting according to the TRACE instruction encountered and leaves this pause point. If no TRACE instruction is executed within the string, the language processor simply pauses again at the same point in the program.

At a pause point:

```

if #AtPause = 0 & #Interactive.#Level & #InhibitTrace = 0 then do
  if #InhibitPauses > 0 then #InhibitPauses = #InhibitPauses-1
  else do
    #TraceInstruction = '0'
  do forever
    call Config_Trace_Query
    if #Outcome == 'No' & #Trace QueryPrior == 'Yes' then do
      /* External request to stop tracing. */
      #Trace_QueryPrior=#Outcome
      #Interactive.#Level = '0'
      #Tracing.#Level = 'N'
      leave
    end
    if #Outcome == 'Yes' & #Trace QueryPrior == 'No' then do
      /* External request for Trace '?R!' */
      #Trace QueryPrior = #Outcome
      #Interactive.#Level = '1'
      #Tracing.#Level = 'R'
      leave
    end
    if \#Interactive.#Level | #TraceInstruction then leave
  /* Accept input for immediate execution. */
  call Config_Trace_Input

```

```

    if length(#Outcome) = 0 | #Outcome == '=' then leave
    #AtPause = #Level
    interpret #Outcome
    #AtPause = 0
    end /* forever loop */
    if #Outcome == '=' then call #Retry /* With no return */
end
end

```

## 11.5 Instruction

### 11.5.1 ADDRESS

For a definition of the syntax of this instruction, see nnn.

An external environment to which commands can be submitted is identified by an environment name. Environment names are specified in the ADDRESS instruction to identify the environment to which a command should be sent.

I/O can be redirected when submitting commands to an external environment. The submitted command's input stream can be taken from an existing stream or from a set of compound variables with a common stem. In the latter case (that is, when a stem is specified as the source for the command's input stream) whole number tails are used to order input for presentation to the submitted command. Stem.0 must contain a whole number indicating the number of compound variables to be presented, and stem. 1 through stem.n (where n=stem.0) are the compound variables to be presented to the submitted command.

Similarly, the submitted command's output stream can be directed to a stream, or to a set of compound variables with a given stem. In the latter case (i.e., when a stem is specified as the destination) compound variables will be created to hold the standard output, using whole number tails as described above. Output redirection can specify a REPLACE or APPEND option, which controls positioning prior to the command's execution. REPLACE is the default.

I/O redirection can be persistently associated with an environment name. The term "environment" is used to refer to an environment name together with the I/O redirections.

At any given time, there will be two environments, the active environment and the alternate environment. When an ADDRESS instruction specifies a command to the environment, any specified I/O redirection applies to that command's execution only, providing a third environment for the duration of the instruction. When an ADDRESS command does not contain a command, that ADDRESS command creates a new active environment, which includes the specified I/O redirection.

The redirections specified on the ADDRESS instruction may not be possible. If the configuration is aware that the command processor named does not perform I/O in a manner compatible with the request, the value of #Env\_Type. may be set to 'UNUSED' as an alternative to 'STEM' and 'STREAM' where those values are assigned in the following code.

In the following code the particular use of #Contains(address, expression) refers to an expression immediately contained in the *address*.

```

Addrinstr:
/* If ADDRESS keyword alone, environments are swapped. */
if \#Contains (address, taken constant),
  & \#Contains (address,valueexp),
  & \#Contains (address, 'WITH') then do
    call EnvAssign TRANSIENT, #Level, ACTIVE, #Level
    call EnvAssign ACTIVE, #Level, ALTERNATE, #Level
    call EnvAssign ALTERNATE, #Level, TRANSIENT, #Level
    return
  end
/* The environment name will be explicitly specified. */
if #Contains(address,taken constant) then
  Name = #Instance(address, taken _ constant)
else
  Name = #Evaluate(valueexp, expression)
if length(Name) > #LimitEnvironmentName then
  call #Raise 'SYNTAX', 29.1, Name

if #Contains(address,expression) then do
  /* The command is evaluated (but not issued) at this point. */
  Command = #Evaluate (address, expression)
  if #Tracing.#Level == 'C' | #Tracing.#Level == 'A' then do
    call #Trace '>>>!'
  end
end

call AddressSetup /* Note what is specified on the ADDRESS
  instruction. */
/* If there is no command, the persistent environment is being set.
  */
if \#Contains(address,expression) then do
  call EnvAssign ACTIVE, #Level, TRANSIENT, #Level
  return
end

call CommandIssue Command /* See nnn */

return /* From Addrinstr */

```

```

AddressSetup:
/* Note what is specified on the ADDRESS instruction,
  into the TRANSIENT environment. */
EnvTail = 'TRANSIENT. '#Level
/* Initialize with defaults. */
#Env_Name.EnvTail = ''
#Env_Type.I.EnvTail = 'NORMAL'
#Env_Type.O.EnvTail = 'NORMAL'
#Env_Type.E.EnvTail = 'NORMAL'
#Env_Resource.I.EnvTail = ''
#Env_Resource.O.EnvTail = '!'
#Env_Resource.E.EnvTail = ''
/* APPEND / REPLACE does not apply to input. */
#Env_Position.I.EnvTail = 'INPUT'
#Env_Position.O.EnvTail = 'REPLACE'
#Env_Position.E.EnvTail = 'REPLACE'

/* If anything follows ADDRESS, it will include the command

```

```

processor name.*/
#Env_Name.EnvTail = Name

/* Connections may be explicitly specified. */
if #Contains (address, connection) then do
  if #Contains(connection,input) then do /* input redirection */
    if #Contains (resourcei, 'STREAM') then do
      #Env_Type.I.EnvTail = 'STREAM'
      #Env_Resource.1.EnvTail=#Evaluate(resourcei, VAR_SYMBOL)
    end
    if #Contains (resourcei, 'STEM') then do
      #Env_Type.I.EnvTail = 'STEM'
      Temp=#Instance (resourcei,VAR_SYMBOL)
      if \#Parses(Temp, stem /* See nnn */) then
        call #Raise 'SYNTAX', 53.3, Temp
      #Env_Resource.I.EnvTail=Temp
    end
  end /* Input */

  if #Contains(connection,output) then /* output redirection */
    call NoteTarget 0

  if #Contains(connection,error) then /* error redirection */
    /* The prose on the description of #Contains specifies that the
       relevant resourceo is used in NoteTarget. */
    call NoteTarget E
  end /* Connection */

return /* from AddressSetup */

NoteTarget:
/* Note the characteristics of an output resource. */
arg Which /* 0 or E */
if #Contains (resourceo, 'STREAM') then do
  #Env_Type.Which.EnvTail='STREAM'
  #Env_Resource.Which.EnvTail=#Evaluate(resourceo, VAR_SYMBOL)
end
if #Contains(resourceo,'STEM') then do
  #Env_Type.Which.EnvTail='STEM'
  Temp=#Instance (resourceo, VAR_SYMBOL)
  if \#Parses(Temp, stem /* See nnn */) then
    call #Raise 'SYNTAX', 53.3, Temp
  #Env_Resource.Which.EnvTail=Temp
end
if #Contains (resourceo,append) then
  #Env_Position.Which.EnvTail='APPEND'
return /* From NoteTarget */

EnvAssign:
/* Copy the values that name an environment and describe its
redirections. */
arg Lhs, LhsLevel, Rhs, RhsLevel
#Env_Name.Lhs.LhsLevel = #Env_Name.Rhs.RhsLevel
#Env_Type.I.Lhs.LhsLevel = #Env_Type.I.Rhs.RhsLevel
#Env_Resource.I.Lhs.LhsLevel = #Env_Resource.I.Rhs.RhsLevel
#Env_Position.I.Lhs.LhsLevel = #Env_Position.I.Rhs.RhsLevel
#Env_Type.0.Lhs.LhsLevel = #Env_Type.0.Rhs.RhsLevel

```

```

#Env_Resource.0.Lhs.LhsLevel = #Env_Resource.0.Rhs.RhsLevel
#Env_Position.0.Lhs.LhsLevel = #Env_Position.0.Rhs.RhsLevel
#Env_Type.E.Lhs.LhsLevel = #Env_Type.E.Rhs.RhsLevel
#Env_Resource.E.Lhs.LhsLevel #Env_Resource.E.Rhs.RhsLevel
#Env_Position.E.Lhs.LhsLevel #Env_Position.E.Rhs.RhsLevel
return

```

### 11.5.2 ARG

For a definition of the syntax of this instruction, see nnn.

The ARG instruction is a shorter form of the equivalent instruction:

```
PARSE UPPER ARGtemplate list
```

### 11.5.3 Assignment

Assignment can occur as the result of executing a clause containing an assignment (see nnn and nnn), or as a result of executing the VALUE built-in function, or as part of the execution of a PARSE instruction. Assignment involves an *expression* and a *VAR\_SYMBOL*. The value of the *expression* is determined; see nnn.

If the *VAR\_SYMBOL* does not contain a period, or contains only one period as its last character, the value is associated with the *VAR\_SYMBOL*:

```
call Var_Set #Pool,VAR_SYMBOL, '0',Value
```

Otherwise, a name is derived, see nnn. The value is associated with the derived name:

```
call Var_Set #Pool,Derived Name,'1',Value
```

### 11.5.4 CALL

For a definition of the syntax of this instruction, see nnn.

The CALL instruction is used to invoke a routine, or is used to control trapping of conditions.

If a *vref* is specified that value is the name of the routine to invoke:

```
if #Contains (call, vref) then
  Name = #Evaluate(vref, var_symbol)
```

If a *taken\_constant* is specified, that name is used.

```
if #Contains (call, taken_constant) then
  Name = #Instance(call, taken_constant)
```

The name is used to invoke a routine, see nnn. If that routine does not return a result the RESULT and .RESULT variables become uninitialized:

```
call Var_Drop #Pool, 'RESULT', '0!'
call Var_Drop #ReservedPool, '.RESULT', '0'
```

If the routine does return a result that value is assigned to RESULT and .RESULT. See nnn for an exception to assigning results.

If the routine returns a result and the trace setting is 'R' or 'I' then a trace with that result and a tag '>>>' shall be produced, associated with the call instruction.

If a *callon\_spec* is specified:

```
If #Contains(call,callon spec) then do
  Condition = #Instance(callon_spec,callable condition)
  #Instruction.Condition.#Level = 'CALL'
  If #Contains(callon spec, 'OFF') then
    #Enabling.Condition.#Level = 'OFF'
  else
    #Enabling.Condition.#Level = 'ON'
  /* Note whether NAME supplied. */
  If Contains (callon spec,taken constant) then
    Name = #Instance (callable condition, taken_constant)
  else
    Name = Condition
  #TrapName.Condition.#Level = Name
end
```

### 11.5.5 Command to the configuration

For a definition of the syntax of a command, see nnn.

A command that is not part of an ADDRESS instruction is processed in the ACTIVE environment.

```
Command = #Evaluate(command, expression)
if #Tracing.#Level == 'C' | #Tracing.#Level == 'A' then
  call #Trace '>>>!'
call EnvAssign TRANSIENT, #Level, ACTIVE, #Level
call CommandIssue Command
```

CommandIssue is also used to describe the ADDRESS instruction:

```
CommandIssue:
  parse arg Cmd
  /* Issues the command, requested environment is TRANSIENT */
  /* This description does not require the command processor to
     understand
     stems, so it uses an altered environment. */
  call EnvAssign PASSED, #Level, TRANSIENT, #Level
  EnvTail = 'TRANSIENT.'#Level

  /* Note the command input. */
  if #Env_Type.I.EnvTail = 'STEM' then do
    /* Check reasonableness of the stem. */
    Stem = #Env_Resource.I.EnvTail
    Lines = value(Stem'0')
    if \datatype(Lines,'W') then
      call #Raise 'SYNTAX',54.1,Stem'0', Lines
    if Lines<0 then
      call #Raise 'SYNTAX',54.1,Stem'0', Lines
    /* Use a stream for the stem */
    #Env_Type.I.PASSED.#Level = 'STREAM'
    call Config_Stream_Unique
    InputStream = #Outcome
```

```

    #Env_Resource.1I.PASSED.#Level = InputStream
    call charout InputStream , ,l
    do j = 1 to Lines
        call lineout InputStream, value(Stem || j)
    end j
    call lineout InputStream
end

/* Note the command output. */
if #Env_Type.0.EnvTail = 'STEM' then do
    Stem = #Env_Resource.0.EnvTail
    if #Env_Position.0.EnvTail == 'APPEND' then do
        /* Check that Stem.0 will accept incrementing. */
        Lines=value (Stem'0');
        if \datatype(Lines,'W') then
            call #Raise 'SYNTAX',54.1,Stem'0', Lines
        if Lines<0 then
            call #Raise 'SYNTAX',54.1,Stem'0', Lines
        end
    else call value Stem'0',0
    /* Use a stream for the stem */
    #Env_Type.0.PASSED.#Level = 'STREAM'
    call Config_Stream_Unique
    #Env_Resource.0.PASSED.#Level = #Outcome
end

/* Note the command error stream. */
if #Env_Type.E.EnvTail = 'STEM' then do
    Stem = #Env_Resource.E.EnvTail
    if #Env_Position.E.EnvTail == 'APPEND' then do
        /* Check that Stem.0 will accept incrementing. */
        Lines=value (Stem'0');
        if \datatype(Lines,'W') then
            call #Raise 'SYNTAX',54.1,Stem'0', Lines
        if Lines<0 then
            call #Raise 'SYNTAX',54.1,Stem'0', Lines
        end
    else call value Stem'0',00
    /* Use a stream for the stem */
    #Env_Type.E.PASSED.#Level = 'STREAM'
    call Config_Stream_Unique
    #Env_Resource.E.PASSED.#Level = #Outcome
end

#API Enabled = '1'
call Var_Reset #Pool
/* Specifying PASSED here implies all the
   components of that environment. */

else if #Indicator='E' | #Indicator='F' then call #Raise 'ERROR', Cmd
return /* From CommandIssue */

```

The configuration may choose to perform the test for message 54.1 before or after issuing the command.

### 11.5.6 DO

For a definition of the syntax of this instruction, see nnn.

The DO instructions is used to group instructions together and optionally to execute them repeatedly.

Executing a *do\_simple* has the same effect as executing a *nop*, except in its trace output. Executing the *do\_ending* associated with a *do\_simple* has the same effect as executing a *nop*, except in its trace output.

A *do\_instruction* that does not contain a *do\_simple* is equivalent, except for trace output, to a sequence of instructions in the following order.

```
#Loop = #Loop+1
```

```

#Iterate.#Loop = #Clause (IterateLabel)
#Once.#Loop = #Clause (OnceLabel)
#Leave.#Loop = #Clause (LeaveLabel)
if #Contains (do specification,assignment) then
    #Identity.#Loop = #Instance(assignment, VAR SYMBOL)
if #Contains (do specification, repexpr) then
    if \datatype(repexpr,'W') then
        call #Raise 'SYNTAX', 26.2,repexpr
    else do
        #Repeat.#Loop = repexpr+0
        if #Repeat.#Loop<0 then
            call #Raise 'SYNTAX',26.2,#Repeat.#Loop
        end
if #Contains (do specification,assignment) then do
    #StartValue.#Loop = #Evaluate (assignment, expression)
    if datatype (#StartValue.#Loop) \== 'NUM' then
        call #Raise 'SYNTAX', 41.6, #StartValue.#Loop
    #StartValue.#Loop = #StartValue.#Loop + 0
    if \#Contains (do specification,byexpr) then
        #By.#Loop = 1
    end
end

```

The following three assignments are made in the order in which 'TO', 'BY' and 'FOR' appear in *docount*; see nnn.

```

if #Contains (do specification, toexpr) then do
    if datatype(toexpr) \== 'NUM' then
        call #Raise 'SYNTAX', 41.4, toexpr
    #To.#Loop = toexpr+0
if #Contains (do specification, byexpr) then do
    if datatype (byexpr) \== 'NUM' then
        call #Raise 'SYNTAX', 41.5, byexpr
    #By.#Loop = byexpr+0
if #Contains (do specification, forexpr) then do
    if \datatype(forexpr, 'W') then
        call #Raise 'SYNTAX', 26.3, forexpr
    #For.#Loop = forexpr+0
    if #For.#Loop <0 then
        call #Raise 'SYNTAX', 26.3, #For.#Loop
    end
if #Contains (do specification,assignment) then do
    call value #Identity.#Loop, #StartValue.#Loop
    end
if #Contains (do specification, 'OVER') then do
    Value = #Evaluate(dorep, expression)
    #OverArray.#Loop = Value ~ makearray
    #Repeat.#Loop = #OverArray~items /* Count this downwards as if
        repexpr. */
    #Identity.#Loop = #Instance(dorep, VAR_SYMBOL)
    end
call #Goto #Once.#Loop /* to OnceLabel */
IterateLabel:
if #Contains (do specification, untilexpr) then do
    Value = #Evaluate(untilexp, expression)
    if Value == '1' then leave
    if Value \== '0' then call #Raise 'SYNTAX', 34.4, Value
    end
end

```

```

if #Contains (do specification, assignment) then do
  t = value (#Identity. #Loop)
  if #Indicator == 'D' then call #Raise 'NOVALUE', #Identity.#Loop
  call value #Identity.#Loop, t + #By.#Loop
end

OnceLabel:
if #Contains (do specification, toexpr) then do
  if #By.#Loop>=0 then do
    if value(#Identity.#Loop) > #To.#Loop then leave
    end
  else do if value(#Identity.#Loop) < #To.#Loop then leave
  end
end
if #Contains(dorep, repexpr) | #Contains(dorep, 'OVER') then do
  if #Repeat.#Loop = 0 then leave
  #Repeat.#Loop = #Repeat.#Loop-1
  if #Contains(dorep, 'OVER') then
    call value #Identity.#Loop, #OverArray[#OverArray~items - #
    Repeat.#Loop]
  end
end
if #Contains (do specification, forexpr) then do
  if #For.#Loop = 0 then leave
  #For.#Loop = #For.#Loop - 1
end
if #Contains (do specification, whileexpr) then do
  Value = #Evaluate(whileexp, expression)
  if Value == '0' then leave
  if Value \== '1' then call #Raise 'SYNTAX', 34.3, Value
end
  #Execute (do instruction, instruction list)
TraceOfEnd:
call #Goto #Iterate.#Loop /* to IterateLabel */
LeaveLabel:
#Loop = #Loop - 1

```

### 11.5.7 DO loop tracing

When clauses are being traced by #TraceSource, due to pos(#Tracing.#Level, 'AIR') > 0, the DO instruction shall be traced when it is encountered and again each time the IterateLabel (see nnn) is encountered. The END instruction shall be traced when the TraceOfEnd label is encountered.

When expressions or intermediates are being traced they shall be traced in the order specified by nnn. Hence, in the absence of conditions arising, those executed prior to the first execution of OnceLabel shall be shown once per execution of the DO instruction; others shall be shown depending on the outcome of the tests.

The code in the DO description:

```

t = value (#Identity. #Loop)
if #Indicator == 'D' then call #Raise 'NOVALUE', #Identity.#Loop
call value #Identity.#Loop, t + #By.#Loop

```

represents updating the control variable of the loop. That assignment is subject to tracing,

and other expressions involving state variables are not. When tracing intermediates, the BY value will have a tag of '>+>'.

### 11.5.8 DROP

For a definition of the syntax of this instruction, see nnn.

The DROP instruction restores variables to an uninitialized state.

The words of the *variable\_list* are processed from left to right.

A word which is a VAR\_SYMBOL, not contained in parentheses, specifies a variable to be dropped. If VAR\_SYMBOL does not contain a period, or has only a single period as its last character, the variable associated with VAR\_SYMBOL by the variable pool is dropped:

```
#Response = Var_Drop (#Pool, VAR_SYMBOL, '0')
```

If VAR\_SYMBOL has a period other than as the last character, the variable associated with VAR\_SYMBOL by the variable pool is dropped by:

```
#Response = Var_Drop (#Pool, VAR_SYMBOL, '1')
```

If the word of the *variable\_list* is a VAR\_SYMBOL enclosed in parentheses then the value of the VAR\_SYMBOL is processed. The value is considered in uppercase:

```
#Value = Config_Upper (#Value)
```

Each word in that value found by the WORD built-in function, from left to right, is subjected to this process:

If the word does not have the syntax of VAR\_SYMBOL a condition is raised:

```
call #Raise 'SYNTAX', 20.1, word
```

Otherwise the VAR\_SYMBOL indicated by the word is dropped, as if that VAR\_SYMBOL were a word of the *variable\_list*.

### 11.5.9 EXIT

For a definition of the syntax of this instruction, see nnn.

The EXIT instruction is used to unconditionally complete execution of a program.

Any *expression* is evaluated:

```
if #Contains(exit, expression) then Value = #Evaluate(exit,  
    expression)  
#Level = 1  
#Pool = #Pool1
```

The opportunity is provided for a final trap.

```
#API Enabled = '1'  
call Var_Reset #Pool  
call Config_Termination  
#API Enabled = '0'
```

The processing of the program is complete. See nnn for what API\_Start returns as the result.

If the normal sequence of execution “falls through” the end of the program; that is, would execute a further statement if one were appended to the program, then the program is terminated in the same manner as an EXIT instruction with no argument.

### 11.5.10 EXPOSE

The expose instruction identifies variables that are not local to the method.

*We need a check that this starts method; similarities with PROCEDURE.*

For a definition of the syntax of this instruction, see nnn.

It is used at the start of a method, after method initialization, to make variables in the receiver’s pool accessible:

```
if \#AllowExpose then call #Raise 'SYNTAX', 17.2
```

The words of the *variable\_list* are processed from left to right.

A word which is a VAR\_SYMBOL, not contained in parentheses, specifies a variable to be made accessible. If VAR\_SYMBOL does not contain a period, or has only a single period as its last character, the variable associated with VAR\_SYMBOL by the variable pool (as a non-tailed name) is given the attribute ‘exposed’.

```
call Var_Expose #Pool, VAR_SYMBOL, '0'
```

If VAR\_SYMBOL has a period other than as last character, the variable associated with VAR\_SYMBOL in the variable pool ( by the name derived from VAR\_SYMBOL, see nnn) is given the attribute ‘exposed’.

```
call Var_Expose #Pool, Derived Name, '1'
```

If the word from the *variable\_list* is a VAR\_SYMBOL enclosed in parentheses then the VAR\_SYMBOL is exposed, as if that VAR\_SYMBOL was a word in the *variable\_list*. The value of the VAR\_SYMBOL is processed. The value is considered in uppercase:

```
#Value = Config_Upper (#Value)
```

the WORD built-in function, from left to right, is subjected to this process:

If the word does not have the syntax of VAR\_SYMBOL a condition is

```
call #Raise 'SYNTAX', 20.1, word
```

VAR\_SYMBOL indicated by the word is exposed, as if that VAR\_SYMBOL were a word of the *variable\_list*.

### 11.5.11 FORWARD

For a definition of the syntax of this instruction, see nnn.

The FORWARD instruction is used to send a message based on the current message.

```
if #Contains (forward, 'ARRAY') & #Contains(forward, 'ARGUMENTS')  
  then  
    call #Raise 'SYNTAX', nn.n
```

### 11.5.12 GUARD

For a definition of the syntax of this instruction, see nnn.

The GUARD instruction is used to conditionally delay the execution of a method.

```
do forever
  Value = #Evaluate( guard, expression)
  if Value == '1' then leave
  if Value \== '0' then call #Raise 'SYNTAX', 34.7, Value

end
*/
```

### 11.5.13 IF

For a definition of the syntax of this instruction, see nnn.

The IF instruction is used to conditionally execute an instruction, or to select between two alternatives. The *expression* is evaluated. If the value is neither '0' nor '1' error 34.1 occurs. If the value is '1', the *instruction* in the *then* is executed. If the value is '0' and *else* is specified, the instruction in the *else* is executed.

In the former case, if tracing clauses, the clause consisting of the THEN keyword shall be traced in addition to the instructions.

In the latter case, if tracing clauses, the clause consisting of the ELSE keyword shall be traced in addition to the instructions.

### 11.5.14 INTERPRET

For a definition of the syntax of this instruction, see nnn.

The INTERPRET instruction is used to execute instructions that have been built dynamically by evaluating an expression.

The *expression* is evaluated.

The HALT condition is tested for, and may be raised, in the same way it is tested at clause termination, see nnn.

The process of syntactic recognition described in clause 6 is applied, with Config\_SourceChar obtaining its results from the characters of the value, in left-to-right order, without producing any EOL or EOS events. When the characters are exhausted, the event EOL occurs, followed by the event EOS. If that recognition would produce any message then the *interpret* raises the corresponding 'SYNTAX' condition.

If the program recognized contains any LABELs then the *interpret* raises a condition:

```
call #Raise 'SYNTAX', 47.1, Label
```

LABEL in the *program*.

Otherwise the *instruction\_list* in the *program* is executed.

### 11.5.15 ITERATE

For a definition of the syntax of this instruction, see nnn.

The ITERATE instruction is used to alter the flow of control within a repetitive DO.

For a definition of the nesting correction, see nnn.

```
#Loop = #Loop - NestingCorrection  
call #Goto #Iterate.#Loop
```

### 11.5.16 Execution of labels

The execution of a label has no effect, other than clause termination activity and any tracing.

```
if #Tracing.#Level=='L' then call #TraceSource
```

### 11.5.17 LEAVE

For a definition of the syntax of this instruction, see nnn.

The LEAVE instruction is used to immediately exit one or more repetitive DOs.

For a definition of the nesting correction, see nnn.

```
#Loop = #Loop - NestingCorrection  
call #Goto #Leave.#Loop
```

### 11.5.18 Message term

*We can do this by reference to method invokation, just as we do CALL by reference to invoking a function.*

### 11.5.19 LOOP

*Shares most of it's definition with repetitive DO.*

### 11.5.20 NOP

For a definition of the syntax of this instruction, see nnn.

The NOP instruction has no effect other than the effects associated with all instructions.

### 11.5.21 NUMERIC

For a definition of the syntax of this instruction, see nnn.

The NUMERIC instruction is used to change the way in which arithmetic operations are carried out.

## NUMERIC DIGITS

For a definition of the syntax of this instruction, see nnn.

NUMERIC DIGITS controls the precision under which arithmetic operations and arithmetic built-in functions will be evaluated.

```
if #Contains(numericdigits, expression) then
    Value = #Evaluate(numericdigits, expression)
else Value = 9
if \datatype(Value, 'W') then
    call #Raise 'SYNTAX', 26.5, Value
Value = Value + 0
if Value <= #Fuzz.#Level then
    call #Raise 'SYNTAX', 33.1, Value
if Value > #Limit Digits then
    call #Raise 'SYNTAX', 33.2, Value
#Digits.#Level = Value
```

## NUMERIC FORM

For a definition of the syntax of this instruction, see nnn.

NUMERIC FORM controls which form of exponential notation is to be used for the results of operations and arithmetic built-in functions.

The value of form is either taken directly from the SCIENTIFIC or ENGINEERING keywords, or by evaluating *valueexp*.

```
if \#Contains (numeric, numericsuffix) then
    Value = 'SCIENTIFIC'
else if #Contains (numericformsuffix, 'SCIENTIFIC') then
    Value = 'SCIENTIFIC'
else
    if #Contains (numericformsuffix, 'ENGINEERING') then
        Value = 'ENGINEERING'
    else do
        Value = #Evaluate (numericformsuffix, valueexp)
        Value = translate (left (Value, 1))
        select
            when Value == 'S' then Value = 'SCIENTIFIC'
            when Value == 'E' then Value = 'ENGINEERING'
            otherwise call #Raise 'SYNTAX', 33.3, Value
        end
    end
end
#Form.#Level = Value
```

## NUMERIC FUZZ

For a definition of the syntax of this instruction, see nnn.

NUMERIC FUZZ controls how many digits, at full precision, will be ignored during a numeric comparison.

```
If #Contains (numericfuzz, expression) then
    Value = #Evaluate (numericfuzz, expression)
```

```

else
    Value = 0
If \datatype(Value,'W') then
    call #Raise 'SYNTAX',26.6,Value
    Value = Value+0
If Value < 0 then
    call #Raise 'SYNTAX',26.6,Value
If Value >= #Digits.#Level then
    call #Raise 'SYNTAX',33.1,#Digits.#Level,Value
#Fuzz.#Level = Value

```

## OPTIONS

For a definition of the syntax of this instruction, see nnn.

The OPTIONS instruction is used to pass special requests to the language processor.

The *expression* is evaluated and the value is passed to the language processor. The language processor treats the value as a series of blank delimited words. Any words in the value that are not recognized by the language processor are ignored without producing an error.

```
call Config_Options (Expression)
```

## PARSE

For a definition of the syntax of this instruction, see nnn.

The PARSE instruction is used to assign data from various sources to variables.

The purpose of the PARSE instruction is to select substrings of the *parse\_fype* under control of the *template\_list*. If the *template\_list* is omitted, or a *template* in the list is omitted, then a template which is the null string is implied.

Processing for the PARSE instruction begins by constructing a value, the source to be parsed.

```

ArgNum = 0
select
    when #Contains (parse type, 'ARG') then do
        ArgNum = 1
        ToParse = #Arg.#Level.ArgNum
    end
    when #Contains (parse type, 'LINEIN') then ToParse = linein('')
    when #Contains (parse type, 'PULL') then do
        /* Acquire from external queue or default input. */
        #Response = Config_Pull()
        if left(#Response, 1) == 'F' then
            call Config_Default_Input
            ToParse = #Outcome
        end
    end
    when #Contains (parse type, 'SOURCE') then
        ToParse = #Configuration #HowInvoked #Source
    when #Contains (parse type, 'VALUE') then
        if \#Contains(parse value, expression) then ToParse = ''
        else ToParse = #Evaluate(parse value, expression)

```

```

when #Contains (parse type, 'VAR') then
  ToParse = #Evaluate (parse var, VAR_SYMBOL)
when #Contains (parse type, 'VERSION') then ToParse = #Version
end
Uppering = #Contains(parse, 'UPPER')

```

The first template is associated with this source. If there are further templates, they are matched against null strings unless 'ARG' is specified, when they are matched against further arguments.

The parsing process is defined by the following routine, ParseData. The *template\_list* is accessed by ParseData as a stemmed variable. This variable Template. has elements which are null strings except for any elements with tails 1,2,3,... corresponding to the tokens of the *template\_list* from left to right.

ParseData:

```

/* Targets will be flagged as the template is examined. */
Target.='0'
/* Token is a cursor on the components of the template,
moved by FindNextBreak. */
Token = 1
/* Tok is a cursor on the components of the template
moved through the target variables by routine WordParse. */
Tok = 1
do forever /* Until commas dealt with. */
  /* BreakStart and BreakEnd indicate the position in the source
  string where there is a break that divides the source. When the
  break
  is a pattern they are the start of the pattern and the position
  just
  beyond it. */
  BreakStart =
  BreakEnd = 1
  SourceEnd = length(ToParse) + 1
  If Uppering then ToParse = translate (ToParse)

  do while Template.Tok \== ' ' & Template.Tok \== ','

    /* Isolate the data to be processed on this iteration. */
    call FindNextBreak /* Also marks targets. */

    /* Results have been set in DataStart which indicates the start
    of the isolated data and BreakStart and BreakEnd which are ready
    for the next iteration. Tok has not changed. */

    /* If a positional takes the break leftwards from the end of the
    previous selection, the source selected is the rest of the string
    , */

    if BreakEnd <= DataStart then
      DataEnd = SourceEnd
    else
      DataEnd = BreakStart

    /* Isolated data, to be assigned from: */
    Data=substr (ToParse,DataStart, DataEnd-DataStart)
    call WordParse /* Does the assignments. */
  end /* while */
end

```

```

if Template.Tok== '.' then Tag='>.>'
else do
    Tag='>=>'
    call value Template.Tok,arg(1)
end
/* Arg(1) is an implied argument of the tracing.
if #Tracing.#Level == 'R' | #Tracing.#Level == 'I' then call #
    Trace Tag
return

```

For a definition of the syntax of this instruction, see nnn.

The PROCEDURE instruction is used within an internal routine to protect all the existing variables by making them unknown to following instructions. Selected variables may be exposed.

It is used at the start of a routine, after routine initialization:

```

if \#AllowProcedure.#Level then call #Raise 'SYNTAX', 17.1
#AllowProcedure.#Level = 0
/* It introduces a new variable pool: */
call #Config_ObjectNew
call var_set (#Outcome,'#UPPER', '0', #Pool) /* Previous #Pool is
    upper from the new
#Pool. */
#Pool=#00Outcome
IsProcedure.#Level='1'
call Var_Empty #Pool

```

If there is a *variable\_list*, it provides access to a previous variable pool.

The words of the *variable\_list* are processed from left to right.

A word which is a VAR\_SYMBOL, not contained in parentheses, specifies a variable to

be made accessible. If VAR\_SYMBOL does not contain a period, or has only a single period as its last character, the variable associated with VAR\_SYMBOL by the variable pool (as a non-tailed name) is given the attribute 'exposed'.

```
call Var_Expose #Pool, VAR_SYMBOL, '0'
```

If VAR\_SYMBOL has a period other than as last character, the variable associated with VAR\_SYMBOL in the variable pool (by the name derived from VAR\_SYMBOL, see nnn) is given the attribute 'exposed'.

```
call Var_Expose #Pool, Derived Name, '1'
```

If the word from the *variable\_list* is a VAR\_SYMBOL enclosed in parentheses then the VAR\_SYMBOL is exposed, as if that VAR\_SYMBOL was a word in the *variable\_list*. The value of the VAR\_SYMBOL is processed. The value is considered in uppercase:

```
#Value = Config_Upper (#Value)
```

Each word in that value found by the WORD built-in function, from left to right, is subjected to this process:

If the word does not have the syntax of VAR\_SYMBOL a condition is raised:

```
call #Raise 'SYNTAX', 20.1, word  
constant
```

Otherwise the VAR\_SYMBOL indicated by the word is exposed, as if that VAR\_SYMBOL were a word of the *variable\_list*.

### 11.5.22 PULL

For a definition of the syntax of this instruction, see nnn.

A PULL instruction is a shorter form of the equivalent instruction:

```
PARSE UPPER PULL template list
```

### 11.5.23 PUSH

For a definition of the syntax of this instruction, see nnn.

The PUSH instruction is used to place a value on top of the stack.

```
If #Contains(push,expression) then  
  Value = #Evaluate (push, expression)  
else  
  Value = ''  
call Config_Push Value
```

### 11.5.24 QUEUE

For a definition of the syntax of this instruction, see nnn.

The QUEUE instruction is used to place a value on the bottom of the stack.

```

If #Contains (queue,expression) then
    Value = #Evaluate (queue, expression)
else
    Value = ''
call Config_Queue Value

```

### 11.5.25 RAISE

The RAISE instruction returns from the current method or routine and raises a condition.

### 11.5.26 REPLY

The REPLY instruction is used to allow both the invoker of a method, and the replying method, to continue executing.

*Must set up for error of expression on subsequent RETURN. ### RETURN* For a definition of the syntax of this instruction, see nnn.

The RETURN instruction is used to return control and possibly a result from a program or internal routine to the point of its invocation.

The RETURN keyword may be followed by an optional expression, which will be evaluated and returned as a result to the caller of the routine.

Any *expression* is evaluated:

```

if #Contains(return,expression) then
    #Outcome = #Evaluate(return, expression)
else if #IsFunction.#Level then
    call #Raise 'SYNTAX', 45.1, #Name.#Level

```

At this point the clause termination occurs and then the following:

If the routine started with a PROCEDURE instruction then the associated pool is taken out of use:

```

if #IsProcedure.#Level then #Pool = #Upper

```

A RETURN instruction which is interactively entered at a pause point leaves the pause point.

```

if #Level = #AtPause then #AtPause = 0

```

The activity at this level is complete:

```

#Level = #Level-1
#NewLevel = #Level+1
1

```

If #Level is not zero, the processing of the RETURN instruction and the invocation is complete. Otherwise processing of the program is completed:

The opportunity is provided for a final trap.

```

#API Enabled = '1'
call Var_Reset #Pool
call Config_Termination
#API Enabled = '0'

```

The processing of the program is complete. See nnn for what API\_Start returns as the result.

### 11.5.27 SAY

For a definition of the syntax of this instruction, see nnn.

The SAY instruction is used to write a line to the default output stream.

```
If #Contains(say,expression) then
  Value = Evaluate (say, expression)
else
  Value = ''
call Config_Default_Output Value
```

For a definition of the syntax of this instruction, see nnn.

The SELECT instruction is used to conditionally execute one of several alternative instructions. When tracing, the clause containing the keyword SELECT is traced at this point.

The #Contains(select\_body, when) test in the following description refers to the items of the optional when repetition in order:

```
LineNum = #LineNumber
Ending = #Clause (EndLabel)
Value=#Evaluate (select body, expression) /* In the required WHEN */
if Value \== '1' & Value \== '0' then
  call #Raise 'SYNTAX',34.2,Value
If Value=='1' then
  call #Execute when, instruction
else do
  do while #Contains (select body, when)
    Value = #Evaluate (when, expression)
    If Value=='1' then do
      call #Execute when, instruction
      call #Goto Ending
    end
    if Value \== '0' then
      call #Raise 'SYNTAX', 34.2, Value
    end /* Of each when */

  If \#Contains(select body, 'OTHERWISE') then
    call #Raise 'SYNTAX', 7.3, LineNum
  If #Contains (select body, instruction list) then
    call #Execute select body, instruction list
  end
EndLabel:
```

When tracing, the clause containing the END keyword is traced at this point.

### 11.5.28 SIGNAL

For a definition of the syntax of this instruction, see nnn.

The SIGNAL instruction is used to cause a change in the flow of control or is used with the ON and OFF keywords to control the trapping of conditions.

```

If #Contains (signal, signal spec) then do
    Condition = #Instance(signal spec, condition)
    #Instruction.Condition.#Level = 'SIGNAL'
    If #Contains (signal spec, 'OFF') then
        #Enabling.Condition.#Level = 'OFF'
    else
        #Enabling.Condition.#Level = 'ON'
    If Contains (signal spec, taken constant) then
        Name = #Instance (condition, taken constant)
    else
        Name = Condition
    #TrapName.Condition.#Level = Name
end

```

If there was a *signal\_spec* this complete the processing of the signal instruction. Otherwise:

```

if #Contains (signal, valueexp)
    then Name #Evaluate(valueexp, expression)
    else Name #Instance(signal, taken constant)

```

The Name matches the first LABEL in the program which has that value. The comparison is made with the '=' operator.

If no label matches then a condition is raised:

```
call #Raise 'SYNTAX', 16.1, Name
```

If the name is a trace-only label then a condition is raised:

```
call #Raise 'SYNTAX', 16.2, Name
```

If the name matches a label, execution continues at that label after these settings:

```

#Loop.#Level = 0
/* A SIGNAL interactively entered leaves the pause point. */
if #Level = #AtPause then #AtPause = 0

```

### 11.5.29 TRACE

For a definition of the syntax of this instruction, see nnn.

The TRACE instruction is used to control the trace setting which in turn controls the tracing of execution of the program.

The TRACE instruction is ignored if it occurs within the program (as opposed to source obtained by Config\_Trace\_Input) and interactive trace is requested (#Interactive.#Level = '1'). Otherwise:

```

#TraceInstruction = '1'
value = ''
if #Contains(trace, valueexp) then Value = #Evaluate(valueexp,
    expression)
if #Contains (trace, taken constant) then Value = #Instance (trace,
    taken constant)
if datatype(Value) == 'NUM' & \datatype(Value, 'W') then
    call #Raise 'SYNTAX', 26.7, Value
if datatype(Value, 'W') then do
    /* Numbers are used for skipping. */

```

```

    if Value>=0 then #InhibitPauses = Value
        else #InhibitTrace = -Value
    end
else do
    if length(Value) = 0 then do
        #Interactive.#Level = '0'
        Value = 'N'
    end
    /* Each question mark toggles the interacting. */
    do while left(Value,1)=='?'
        #Interactive.#Level = \#Interactive.#Level
        Value = substr(Value,2)
    end
    if length(Value) \= 0 then do
        Value = translate( left(Value,1) )
        if verify(Value, 'ACEFILNOR') > 0 then
            call #Raise 'SYNTAX', 24.1, Value
        if Value=='00' then #Interactive.#Level='0'
        end
        #Tracing.#Level = Value
    end
end

```

### 11.5.30 Trace output

If #NoSource is '1' there is no trace output.

The routines #TraceSource and #Trace specify the output that results from the trace settings. That output is presented to the configuration by Config\_Trace\_Output as lines. Each line has a clause identifier at the left, followed by a blank, followed by a three character tag, followed by a blank, followed by the trace data.

The width of the clause identifier shall be large enough to hold the line number of the last line in the program, and no larger. The clause identifier is the source program line number, or all blank if the line number is the same as the previous line number indicated and no execution with trace Off has occurred since. The line number is right-aligned with leading zeros replaced by blank characters.

When input at a pause is being executed (#AtPause \= 0), #Trace does nothing when the tag is not '+++ '.

When input at a pause is being executed, #TraceSource does nothing.

If #InhibitTrace is greater than zero, #TraceSource does nothing except decrement #InhibitTrace. Otherwise, unless the current clause is a null clause, #TraceSource outputs all lines of the source program which contain any part of the current clause, with any characters in those lines which are not part of the current clause and not other\_blank\_characters replaced by blank characters. The possible replacement of other\_blank\_characters is defined by the configuration. The tag is '\*-\* ', or if the line is not the first line of the clause. '\*,\* '.

#Trace output also has a clause identifier and has a tag which is the argument to the #Trace invocation. The data is truncated, if necessary, to #Limit\_TraceData characters. The data is enclosed by quotation marks and the quoted data preceded by two blanks. If the data is truncated, the trailing quote has the three characters '...' appended.

- when `#Tracing.#Level` is 'C' or 'E' or 'F' or 'N' or 'A' and the tag is '>>>' then the data is the value of the command passed to the environment;
- when the tag is '+++' then the data is the four characters 'RC "' concatenated with the character '"';
- when `#Tracing.#Level` is 'l' or 'R' the data is the most recently evaluated value.

Trace output can also appear as the result of a 'SYNTAX' condition occurring, irrespective of the trace setting. If a 'SYNTAX' condition occurs and it is not trapped by SIGNAL ON SYNTAX, then the clause in error shall be traced, along with a traceback. A traceback is a display of each active CALL and INTERPRET instruction, and function invocation, displayed in reverse order of execution, each with a tag of '+++'.

### 11.5.31 USE

For a definition of the syntax of this instruction, see nnn.

The USE instruction assigns the values of arguments to variables.

*Better not say copies since COPY method has different semantics.*

The optional VAR\_SYMBOL positions, positions 1, 2, ..., of the instruction are considered from left to right. If the position has a VAR\_SYMBOL then its value is assigned to:

```
if #ArgExists.Position then
call Value VAR_SYMBOL, #Arg.Position
else
```

*Messy because VALUE bif won't DROP and var\_drop needs to know if compound.*

## 11.6 Conditions and Messages

When an error occurs during execution of a program, an error number and message are associated with it. The error number has two parts, the error code and the error subcode. These are the integer and decimal parts of the error number. Subcodes beginning or ending in zero are not used.

Error codes in the range 1 to 90 and error subcodes up to .9 are reserved for errors described here and for future extensions of this standard.

Error number 3 is available to report error conditions occurring during the initialization phase; error number 2 is available to report error conditions during the termination phase. These are error conditions recognized by the language processor, but the circumstances of their detection is outside of the scope of this standard.

The ERRORTXT built-in function returns the text as initialized in nnn when called with the 'Standard' option. When the 'Standard' option is omitted, implementation-dependent text may be returned.

When messages are issued any message inserts are replaced by actual values.

The notation for detection of a condition is:

```
call #Raise Condition, Arg2, Arg3, Arg4, Arg5, Arg6
```

Some of the arguments may be omitted. In the case of condition 'SYNTAX' the arguments are the message number and the inserts for the message. In other cases the argument is a further description of the condition.

The action of the program as a result of a condition is dependent on any *signal\_spec* and *callon\_spec* in the program.

### 11.6.1 Raising of conditions

The routine #Raise corresponds to raising a condition. In the following definition, the instructions containing SIGNAL VALUE and INTERPRET denote transfers of control in the program being processed. The instruction EXIT denotes termination. If not at an interactive pause, this will be termination of the program, see nnn, and there will be output by Config\_Trace\_Output of the message (with prefix \_ see nnn) and tracing (see nnn). If at an interactive pause (#AtPause \= 0), this will be termination of the interpretation of the interactive input; there will be output by Config\_Trace\_Output of the message (without traceback) before continuing. The description of the continuation is in nnn after the "interpret #Outcome" instruction.

The instruction "interpret 'CALL' #TrapName.#Condition.#Level" below does not set the variables RESULT and .RESULT; any result returned is discarded.

```
#Raise:
/* If there is no argument, this is an action which has been delayed
   from the time the
condition occurred until an appropriate clause boundary. */
if \arg(1,'E') then do
    Description = #PendingDescription. #Condition. #Level
    Extra = #PendingExtra.#Condition. #Level
end
else do
    #Condition = arg(1)
    if #Condition \== 'SYNTAX' then do
        Description = arg(2)
        Extra = arg(3)
    end
    else do
        Description = #Message(arg(2),arg(3),arg(4),arg(5))
        call Var_Set #ReservedPool, '.MN', 0, arg(2)
        Extra = '!'
    end
end

/* The events for disabled conditions are ignored or cause
   termination. */
if #Enabling.#Condition.#Level == 'OFF' | #AtPause \= 0 then do
    if #Condition \== 'SYNTAX' & #Condition \== 'HALT' then
        return /* To after use of #Raise. */
    if #Condition == 'HALT' then Description = #Message(4.1,
        Description)
        exit /* Terminate with Description as the message. */
    end

/* SIGNAL actions occur as soon as the condition is raised. */
if #Instruction.#Condition.#Level == '"SIGNAL' then do
```

```

#ConditionDescription.#Level = Description
#ConditionExtra.#Level = Extra
#ConditionInstruction.#Level = 'SIGNAL'
#Enabling.#Condition.#Level = 'OFF'
signal value #TrapName.#Condition.#Level
end

/* All CALL actions are initially delayed until a clause boundary. */
if arg(1,'E') then do
  /* Events within the handler are not stacked up, except for one
  extra HALT while a first is being handled. */
  EventLevel = #Level
  if #Enabling.#Condition.#Level == 'DELAYED' then do
    if #Condition \== 'HALT' then return
    EventLevel = #EventLevel.#Condition.#Level
    if #PendingNow.#Condition.EventLevel then return
    /* Setup a HALT to come after the one being handled. */
    end
  /* Record a delayed event. */
  #PendingNow.#Condition.EventLevel = '1'
  #PendingDescription.#Condition.EventLevel = Description
  #PendingExtra.#Condition.EventLevel = Extra
  #Enabling.#Condition.EventLevel = 'DELAYED'
  return
  end
/* Here for CALL action after delay. */
/* Values for the CONDITION built-in function. */
#Condition.#NewLevel = #Condition
#ConditionDescription.#NewLevel = #PendingDescription.#Condition.#
  Level
#ConditionExtra.#NewLevel = #PendingExtra.#Condition.#Level
#ConditionInstruction.#NewLevel = 'CALL'
interpret 'CALL' #TrapName.#Condition.#Level
#Enabling.#Condition.#Level = 'ON'
return /* To clause termination */

```

## 11.6.2 Messages during execution

The state function #Message corresponds to constructing a message.

This definition is for the message text in nnn. Translations in which the message inserts are in a different order are permitted.

In addition to the result defined below, the values of MsgNumber and #LineNumber shall be shown when a message is output. Also there shall be an indication of whether the error occurred in code executed at an interactive pause, see nnn.

Messages are shown by writing them to the default error stream.

```

#Message:
  MsgNumber = arg(1)
  if #NoSource then MsgNumber = MsgNumber % 1 /* And hence no
  inserts */
  Text = #ErrorText.MsgNumber
  Expanded = ''

  do Index = 2

```

```

    parse var Text Begin '<' Insert '>' +1 Text
    if Insert = '' then leave
    Insert = arg(Index)
    if length(Insert) > #Limit MessageInsert then
        Insert = left(Insert,#Limit MessageInsert)'...'
    Expanded = Expanded || Begin || Insert
end

Expanded = Expanded || Begin
say Expanded
return

```

## Built-in functions

### 12.1 Notation

The built-in functions are defined mainly through code. The code refers to state variables. This is solely a notation used in this standard.

The code refers to functions with names that start with 'Config\_'; these are the functions described in section nnn.

The code is specified as an external routine that produces a result from the values #Bif (which is the name of the built-in function), #Bif\_Arg.0 (the number of arguments), #Bif\_Arg.i and #Bif\_ArgExists.i (which are the argument data.)

The value of #Level is the value for the clause which invoked the built-in function.

The code either returns the result of the built-in or exits with an indication of a condition that the invocation of the built-in raises.

The code below uses built-in functions. Such a use invokes another use of this code with a new value of #Level. On these invocations, the CheckArgs function is not relevant.

Numeric settings as follows are used in the code. When an argument is being checked as a number by 'NUM' or 'WHOLENUM' the settings are those current in the caller. When an argument is being checked as an integer by an item containing 'WHOLE' the settings are those for the particular built-in function. Elsewhere the settings have sufficient numeric digits to avoid values which would require exponential notation.

### 12.2 Routines used by built-in functions

The routine CheckArgs is concerned with checking the arguments to the built-in. The routines Time2Date and Leap are for date calculations. ReRadix is used for radix conversion. The routine Raise raises a condition and does not return.

#### 12.2.1 Argument checking

```
/* Check arguments. Some further checks will be made in particular
   built-ins.*/
/* The argument to CheckArgs is a checklist for the allowable
   arguments. */

/* NUM, WHOLENUM and WHOLE have a side-effect, 'normalizing' the
   number. */
```

```

/* Calls to raise syntax conditions will not return. */

CheckArgs:
CheckList = arg(1) /* This refers to the argument of CheckArgs. */

/* Move the checklist information from a string to individual
   variables */
ArgType. = ''
ArgPos = 0 /* To count arguments */
MinArgs = 0
do j = 1 to length (CheckList)
  ArgPos = ArgPos+1
  /* Count the required arguments. */
  if substr(CheckList,j,1) == 'r' then MinArgs = MinArgs + 1
  /* Collect type information. */
  do while j < length(CheckList)
    j=eajae1
    t = substr(CheckList,j,1)
    if t==' ' then leave
    ArgType.ArgPos = ArgType.ArgPos || t
  end
  /* A single space delimits parts. */
end j
MaxArgs = ArgPos

/* Check the number of arguments to the built-in, in this instance.
   */
NumArgs = #Bif Arg.0

if NumArgs < MinArgs then call Raise 40.3, MinArgs
if NumArgs > MaxArgs then call Raise 40.4, MaxArgs

/* Check the type(s) of the arguments to the built-in. */
do ArgPos = 1 to NumArgs
  if #Bif ArgExists.ArgPos then
    call CheckType
  else
    if ArgPos <= MinArgs then call Raise 40.5, ArgPos
  end ArgPos
end ArgPos

/* No errors found by CheckArgs. */

return
CheckType:
Value = #Bif Arg.ArgPos
Type = ArgType.ArgPos
select
when Type == 'ANY' then nop /* Any string */
when Type == 'NUM' then do /* Any number */

/* This check is made with the caller's digits setting. */
if \Cdatatype(Value, 'N') then

return r

```

## 12.2.2 Raising the SYNTAX condition

Raise:

```
/* These 40.nn messages always include the built-in name as an insert
   */
call #Raise 'SYNTAX', arg(1), #Bif, arg(2), arg(3), arg(4)
/* #Raise does not return. */
```

## 12.3 Character built-in functions

These functions process characters or words in strings. Character positions are numbered from one at the left. Words are delimited by blanks and their equivalents, word positions are counted from one at the left.

### 12.3.1 ABBREV

ABBREV returns '1' if the second argument is equal to the leading characters of the first and the length of the second argument is not less than the third argument.

```
call CheckArgs 'rANY rANY oWHOLE>=0'
```

```
Subject #Bif Arg.1
```

```
Subj #Bif Arg.2
```

```
if #Bif_ArgExists.3 then Length = #Bif Arg.3
else Length = length (Subj)
```

```
Cond1 = length(Subject) >= length(Subj)
Cond2 = length(Subj) >= Length
Cond3 = substr(Subject, 1, length(Subj)) == Subj
```

```
return Cond1 & Cond2 & Cond3
```

### 12.3.2 CENTER

CENTER returns a string with the first argument centered in it. The length of the result is the second argument and the third argument specifies the character to be used for padding.

```
call CheckArgs 'rANY rWHOLE>=0 oPAD'
```

```
String = #Bif Arg.1
```

```
Length = #Bif Arg.2
```

```
if #Bif_ArgExists.3 then Pad = #Bif Arg.3
else Pad = ' '!
```

```
Trim = length(String) - Length
```

```
if Trim > 0 then
return substr(String, Trim % 2 + 1, Length)
```

```
return overlay(String, copies(Pad, Length), -Trim % 2 + 1)
```

### 12.3.3 CENTRE

This is an alternative spelling for the CENTER built-in function.

### 12.3.4 CHANGESTR

CHANGESTR replaces all occurrences of the first argument within the second argument, replacing them with the third argument.

```
call CheckArgs '"rANY rANY rANY'
```

```
Output = ''
Position = 1
do forever
  FoundPos = pos(#Bif Arg.1, #Bif Arg.2, Position)
  if FoundPos = 0 then leave
  Output = Output || substr(#Bif Arg.2, Position, FoundPos - Position)
  Position = FoundPos + length(#Bif Arg.1)
end
return Output || substr(#Bif Arg.2, Position)
```

### 12.3.5 COMPARE

COMPARE returns '0' if the first and second arguments have the same value. Otherwise, the result is the position of the first character that is not the same in both strings.

```
call CheckArgs 'rANY rANY oPAD'
```

```
Str1 = #Bif_Arg.1
```

```
Str2 = #Bif_Arg.2
```

```
if #Bif_ArgExists.3 then Pad
else Pad
```

```
#Bif Arg.3
```

```
/* Compare the strings from left to right one character at a time */
if length(Str1) > length(Str2) then do
```

```
Length = length(Str1)
```

```
Str2=left (Str2, Length, Pad)
```

```
end
else do
```

```
Length = length(Str2)
```

```
Str1=left (Str1, Length, Pad)
```

```

end

do i= 1 to Length
if substr(Str1, i, 1) \== substr(Str2, i, 1) then return i
end

return 0

```

### 12.3.6 COPIES

COPIES returns concatenated copies of the first argument. The second argument is the number of copies.

```

call CheckArgs '"rANY rWHOLE>=0'
Output = ''
do #Bif Arg.2
Output = Output || #Bif_Arg.1
end

return Output

```

### 12.3.7 COUNTSTR

COUNTSTR counts the appearances of the first argument in the second argument.

```

call CheckArgs '"rANY rANY'

Output = 0

Position = pos (#Bif Arg.1,#Bif Arg.2)

do while Position > 0
Output = Output + 1
Position = pos(#Bif Arg.1, #Bif Arg.2, Position + length(#Bif Arg.1))
end

return Output

```

### 12.3.8 DATATYPE

DATATYPE tests for characteristics of the first argument. The second argument specifies the particular test.

```

call CheckArgs 'rANY oABLMNSUWX'

/* As well as returning the type, the value for a 'NUM' is set in
#DatatypeResult. This is a convenience when DATATYPE is used

by CHECKARGS. */

String = #Bif Arg.1

end

return Outcome

```

### 12.3.9 DELSTR

DELSTR deletes the sub-string of the first argument which begins at the position given by the second argument. The third argument is the length of the deletion.

```

call CheckArgs 'rANY rWHOLE>0 oWHOLE>=0'
String #Bif Arg.1

Num #Bif Arg.2
if #Bif_ArgExists.3 then Len = #Bif_Arg.3

if Num > length(String) then return String

Output = substr(String, 1, Num - 1)
if #Bif_ArgExists.3 then
if Num + Len <= length(String) then
Output = Output || substr(String, Num + Len)
return Output

```

### 12.3.10 DELWORD

DELWORD deletes words from the first argument. The second argument specifies position of the first word to be deleted and the third argument specifies the number of words.

```

call CheckArgs 'rANY rWHOLE>0 oWHOLE>=0'
String #Bif Arg.1

Num #Bif Arg.2
if #Bif_ArgExists.3 then Len = #Bif_Arg.3

if Num > words(String) then return String

EndLeft = wordindex(String, Num) - 1
Output = left(String, EndLeft)
if #Bif_ArgExists.3 then do
BeginRight = wordindex(String, Num + Len)

if BeginRight>0 then
Output =

end
return Output

```

### 12.3.11 INSERT

Output || substr(String, BeginRight)

INSERT insets the first argument into the second. The third argument gives the position of the character before the insert and the fourth gives the length of the insert. The fifth is the padding character.

```
call CheckArgs
```

```
New #Bif_ Arg.1  
Target #Bif Arg.2  
if #Bif_ArgExists.3
```

```
then  
else  
then  
else  
then  
else
```

```
Num  
Num  
Length = #Bif Arg.4  
Length = length (New)  
Pad #Bif Arg.5  
Pad ro
```

```
#Bif Arg.3  
0
```

```
if #Bif_ArgExists.4
```

```
if #Bif_ArgExists.5
```

```
return left(Target, Num, Pad)  
left (New, Length, Pad),  
substr(Target, Num + 1)
```

### 12.3.12 LASTPOS

/\* To left of insert /\* New string inserted // To right of insert

```
'rANY rANY oWHOLE>=0 oWHOLE>=0 oPAD'
```

```
*/  
*/
```

LASTPOS returns the position of the last occurrence of the first argument within the second. The third

argument is a starting position for the search.

```
call CheckArgs 'rANY rANY oWHOLE>0'
```

```
Needle = #Bif_Arg.1  
Haystack = #Bif Arg.2  
if #Bif_ArgExists.3 then Start = #Bif_Arg.3
```

```

else Start = length(Haystack)

NeedleLength = length (Needle)
if NeedleLength = 0 then return 0
Start = Start - NeedleLength + 1
do i= Start by -1 while i > 0
if substr(Haystack, i, NeedleLength)
end i
return 0

```

### 12.3.13 LEFT

LEFT returns characters that are on the left of the first argument.  
length of the result and the third is the padding character.

```

call CheckArgs 'rANY rWHOLE>=0 oPAD'

if #Bif_ArgExists.3 then Pad
else Pad

#Bif Arg.3

return substr(#Bif Arg.1, 1, #Bif_ Arg.2, Pad)

```

### 10.1.14 LENGTH

Needle then return i

The second argument specifies the

Length returns a count of the number of characters in the argument.

```

call CheckArgs 'rANY'

String = #Bif Arg.1

#Response = Config Length(String)

Length = #Outcome

call Config Substr #Response, 1

if #Outcome \== 'E' then return Length

/* Here if argument was not a character string.
call Config C2B String
call #Raise 'SYNTAX',

23.1, b2x(#Outcome)

*/
/* No return to here */

```

### 12.3.14 OVERLAY

OVERLAY overlays the first argument onto the second. The third argument is the starting position of the overlay. The fourth argument is the length of the overlay and the fifth is the padding character.

```
call CheckArgs 'rANY rANY oWHOLE>0 o0WHOLE>=0 oPAD'
```

```
New = #Bif_Arg.1
```

```
Target = #Bif_Arg.2
```

```
if #Bif_ArgExists.3 then Num = #Bif_Arg.3
else Num = 1
```

```
if #Bif_ArgExists.4 then Length = #Bif_Arg.4
else Length = length (New)
```

```
if #Bif_ArgExists.5 then Pad = #Bif_Arg.5
else Pad = ' '
return left(Target, Num - 1, Pad), /* To left of overlay */
|| left (New, Length, Pad), /* New string overlaid */
|| substr (Target, Num + Length) /* To right of overlay */
```

10.1.16 POS

POS returns the position of the first argument within the second.

```
call CheckArgs 'rANY rANY oWHOLE>0'
```

```
Needle #Bif_Arg.1
```

```
Haystack = #Bif_Arg.2
```

```
if #Bif_ArgExists.3 then Start
else Start
```

```
#Bif_Arg.3
1
```

```
if length(Needle) = 0 then return 0
```

```
do i = Start to length (Haystack) +1-length (Needle)
if substr(Haystack, i, length(Needle)) == Needle then return i
end i
```

```
return 0
```

### 12.3.15 REVERSE

REVERSE returns its argument, swapped end for end.

```
call CheckArgs 'rANY'
```

```
String
```

```
#Bif_Arg.1
Output = ''
do i= 1 to length (String)
```

```

Output = substr(String,i,1) || Output
end
return Output

```

### 12.3.16 RIGHT

RIGHT returns characters that are on the right of the first argument. The second argument specifies the length of the result and the third is the padding character.

```

call CheckArgs 'rANY rWHOLE>=0 oPAD'

String = #Bif Arg.1
Length = #Bif Arg.2
if #Bif_ArgExists.3 then Pad

#Bif Arg.3
else Pad '

Trim = length(String) - Length
if Trim >= 0 then return substr(String,Trim + 1)
return copies(Pad, -Trim) || String /* Pad string on the left */

```

### 12.3.17 SPACE

SPACE formats the blank-delimited words in the first argument with pad characters between each word. The second argument is the number of pad characters between each word and the third is the pad character.

```

call CheckArgs 'rANY o0WHOLE>=0 oPAD'

String = #Bif Arg.1

if #Bif_ArgExists.2 then Num = #Bif_ Arg.2
else Num = 1
if #Bif_ArgExists.3 then Pad = #Bif Arg.3
else Pad = ' '
Padding = copies(Pad, Num)
Output = subword(String, 1, 1)
do i = 2 to words (String)
Output = Output || Padding || subword(String, i, 1)

end
return Output

```

### 12.3.18 STRIP

STRIP removes characters from its first argument. The second argument specifies whether the deletions are leading characters, trailing characters or both. Each character deleted is equal to the third argument, or equivalent to a blank if the third argument is omitted.

```

call CheckArgs 'rANY oLTB oPAD'

String = #Bif Arg.1
if #Bif_ArgExists.2 then Option = #Bif Arg.2
else Option = 'B'
if #Bif_ArgExists.3 then Unwanted = #Bif_ Arg.3
else Unwanted = #AllBlanks<Index "#AllBlanks" # "" >

if Option == 'L' | Option == 'B' then do
/* Strip leading characters */
do while String \== '' & pos(left(String, 1), Unwanted) > 0
String = substr(String, 2)
end
end

if Option == 'T' | Option == 'B' then do
/* Strip trailing characters */
do while String \== '' & pos(right(String, 1), Unwanted) > 0
String = left(String, length(String) -1)
end /* of while */
end
return String

```

### 12.3.19 SUBSTR

SUBSTR returns a sub-string of the first argument. The second argument specifies the position of the first character and the third specifies the length of the sub-string. The fourth argument is the padding character.

```

call CheckArgs 'rANY rWHOLE>0 o0WHOLE>=0 oPAD'

String = #Bif Arg.1
Num = #Bif_ Arg.2
if #Bif_ArgExists.3 then Length = #Bif Arg.3
else Length = max(length (String) +1-Num, 0)
if #Bif_ArgExists.4 then Pad = #Bif_ Arg.4
else Pad = ' '!
Output = ''
do Length
#Response Config Substr(String,Num) /* Attempt to fetch character.*/
Character #Outcome

Num = Num + 1
call Config Substr #Response,1 /* Was there such a character? */
if #Outcome == 'E' then do

/* Here if argument was not a character string. */

call Config C2B String
call #Raise 'SYNTAX', 23.1, b2x(#Outcome)
/* No return to here */

end
if #Outcome == 'M' then Character = Pad
Output=Output | | Character
end

```

```
return Output
```

### 12.3.20 SUBWORD

SUBWORD returns a sub-string of the first argument, comprised of words. The second argument is the position in the first argument of the first word of the sub-string. The third argument is the number of words in the sub-string.

```
call CheckArgs 'rANY rWHOLE>0 oWHOLE>=0'

String #Bif Arg.1
Num #Bif Arg.2

if #Bif_ ArgExists.3 then Length
else Length

#Bif_Arg.3
length(String) /* Avoids call */
/* to WORDS() */

if Length = 0 then return ''

/* Find position of first included word */
Start = wordindex (String, Num)

if Start = 0 then return '' /* Start is beyond end */

/* Find position of first excluded word */
End = wordindex (String, Num+Length)
if End = 0 then End = length(String)+1

Output=substr (String, Start, End-Start)

/* Drop trailing blanks */

do while Output \== ''
if pos (right (Output,1),#A11Blanks) = 0 then leave
Output = left (Output, length (Output) -1)
end

return Output
```

### 12.3.21 TRANSLATE

TRANSLATE returns the characters of its first argument with each character either unchanged or translated to another character.

```
call CheckArgs 'rANY oANY oANY oPAD'
String = #Bif Arg.1
/* If neither input nor output tables, uppercase. */
if \#Bif_ ArgExists.2 & \#Bif_ArgExists.3 then do
Output = ''
```

```

do j=1 to length (String)
#Response = Config Upper (substr (String,j,1))

Output = Output || #Outcome
end j

return Output

end

/* The input table defaults to all characters. */
if \#Bif ArgExists.3 then do
#Response = Config Xrange()
Tablei = #Outcome
end
else Tablei = #Bif_Arg.3
/* The output table defaults to null */
if #Bif_ArgExists.2 then Tableo = #Bif Arg.2
else Tableo = ''
/* The tables are made the same length */
if #Bif_ArgExists.4 then Pad = #Bif_ Arg.4
else Pad = ' '
Tableo=left (Tableo, length (Tablei) , Pad)

107
Output=''
do j=1 to length (String)
c=substr (String,j,1)
k=pos(c,Tablei)
if k=0 then Output=Output ||c
else Output=Output | | substr (Tableo,k,1)
end j
return Output

```

### 12.3.22 VERIFY

VERIFY checks that its first argument contains only characters that are in the second argument, or that it contains no characters from the second argument; the third argument specifies which check is made. The result is '0', or the position of the character that failed verification. The fourth argument is a starting position for the check.

```

call CheckArgs 'rANY rANY oMN oWHOLE>0'

String = #Bif Arg.1

Reference = #Bif_Arg.2

if #Bif_ ArgExists.3 then Option #Bif Arg.3
else Option 'N!'

if #Bif_ ArgExists.4 then Start = #Bif_Arg.4
else Start = 1

Last = length(String)
if Start > Last then return 0
if Reference == '' then

```

```

if Option == 'N' then return Start
else return 0

do i = Start to Last
t = pos(substr(String, i, 1), Reference)
if Option == 'N' then do
if t = 0 then return i /* Return position of NoMatch character. */
end
else
if t > 0 then return i /* Return position of Matched character. */
end i
return 0

```

### 12.3.23 WORD

WORD returns the word from the first argument at the position given by the second argument.

```

call CheckArgs 'rANY rwWHOLE>0'

return subword(#Bif Arg.1, #Bif_Arg.2, 1)

```

### 12.3.24 WORDINDEX

WORDINDEX returns the character position in the first argument of a word in the first argument. The second argument is the word position of that word.

```

call CheckArgs 'rANY rwWHOLE>0'

String
Num

#Bif Arg.1
#Bif Arg.2

/* Find starting position */

Start = 1
Count = 0
do forever
Start = verify(String, #AllBlanks<Index "#AllBlanks" # "" >, 'N',
Start) /*
Find non-blank */
if Start = 0 then return 0 /* Start is beyond end */
Count = Count + 1 /* Words found */
if Count = Num then leave
Start = verify(String, #AllBlanks<Index "#AllBlanks" # "" >, 'M',
Start + 1) /*

Find blank */

if Start = 0 then return 0 /* Start is beyond end */
end
return Start

```

### 12.3.25 WORDLENGTH

WORDLENGTH returns the number of characters in a word from the first argument. The second argument is the word position of that word.

```
call CheckArgs 'rANY rwWHOLE>0'
return length(subword(#Bif Arg.1, #Bif_Arg.2, 1))
```

### 12.3.26 WORDPOS

WORDPOS finds the leftmost occurrence in the second argument of the sequence of words in the first argument. The result is '0' or the word position in the second argument of the first word of the matched sequence. Third argument is a word position for the start of the search.

```
call CheckArgs 'rANY rANY oWHOLE>0'
Phrase = #Bif_Arg.1
String = #Bif Arg.2
if #Bif_ArgExists.3 then Start = #Bif_Arg.3
else Start = 1
Phrase = space (Phrase)
PhraseWords = words (Phrase)
if PhraseWords = 0 then return 0
String = space (String)
StringWords = words (String)
do WordNumber = Start to StringWords - PhraseWords + 1
if Phrase == subword(String, WordNumber, PhraseWords) then
return WordNumber
end WordNumber
return 0
```

### 12.3.27 WORDS

WORDS counts the number of words in its argument.

```
call CheckArgs 'rANY'
do Count = 0 by 1
if subword(#Bif Arg.1, Count + 1) == '' then return Count
end Count
```

### 12.3.28 XRANGE

XRANGE returns an ordered string of all valid character encodings in the specified range.

```
call CheckArgs 'oPAD oPAD'
```

```

if \#Bif_ArgExists.1 then #Bif_Arg.1 mr
if \#Bif_ArgExists.2 then #Bif Arg.2
#Response = Config Xrange(#Bif Arg.1, #Bif Arg.2)
return #Outcome

```

## 12.4 Arithmetic built-in functions

These functions perform arithmetic at the numeric settings current at the invocation of the built-in function. Note that CheckArgs formats any 'NUM' (numeric) argument.

### 12.4.1 ABS

ABS returns the absolute value of its argument.

```

call CheckArgs 'rNUM'
Number=#Bif Arg.1

if left (Number,1) = '-' then Number = substr (Number, 2)
return Number

```

### 12.4.2 FORMAT

FORMAT formats its first argument. The second argument specifies the number of characters to be used for the integer part and the third specifies the number of characters for the decimal part. The fourth argument specifies the number of characters for the exponent and the fifth determines when exponential notation is used.

```

call CheckArgs,
'rNUM OWHOLE>=0 OWHOLE>=0 OWHOLE>=0 OWHOLE>=0'

if #Bif_ArgExists.2 then Before #Bif Arg.2
if #Bif_ArgExists.3 then After #Bif Arg.3
if #Bif_ArgExists.4 then Expp #Bif Arg.4

```

### 12.4.3 MAX

MAX returns the largest of its arguments.

```

if #Bif_Arg.0 <1 then
call Raise 40.3, 1
call CheckArgs 'rNUM' ||copies(' rNUM', #Bif Arg.0 - 1)

Max = #Bif Arg.1

do i = 2 to #Bif Arg.0 by 1
Next = #Bif Arg.i
if Max < Next then Max = Next
end i

return Max

```

### 12.4.4 MIN

MIN returns the smallest of its arguments.

```

if #Bif_Arg.0 <1 then
call Raise 40.3, 1
call CheckArgs 'rNUM' ||copies(' rNUM', #Bif Arg.0 - 1)

Min = #Bif Arg.1

do i = 2 to #Bif Arg.0 by 1
Next = #Bif Arg.i
if Min > Next then Min = Next
end i

return Min

```

### 12.4.5 SIGN

SIGN returns '1', '0' or '-1' according to whether its argument is greater than, equal to, or less than zero.

```

call CheckArgs 'rNUM'

Number = #Bif Arg.1

```

```

select
when Number < 0 then Output = -1
when Number = 0 then Output = 0
when Number > 0 then Output = 1
end
return Output

```

### 12.4.6 TRUNC

TRUNC returns the integer part of its argument, or the integer part plus a number of digits after the decimal point, specified by the second argument.

```

call CheckArgs 'rNUM oWHOLE>=0'

Number = #Bif Arg.1
if #Bif_ArgExists.2 then Num

#Bif Arg.2
else Num 0

Integer =(10**Num * Number) %1
if Num=0 then return Integer

t=length (Integer) -Num
if t<=0 then return '0.'right(Integer,Num,'0')
else return insert('.',Integer,t)

```

## 12.5 State built-in functions

These functions return values from the state of the execution.

### 12.5.1 ADDRESS

ADDRESS returns the name of the environment to which commands are currently being submitted. Optionally, under control by the argument, it also returns information on the targets of command output and the source of command input.

```

call CheckArgs 'oEINO'

if #Bif_ArgExists.1 then Option1 = #Bif_Arg.1
else Option1='N'

if Option1 == 'N' then return #Env_Name.ACTIVE. #Level

Tail = Option1' .ACTIVE. '#Level
return #Env_Position.Tail #Env_Type.Tail #Env_Resource.Tail

```

### 12.5.2 ARG

ARG returns information about the argument strings to a program or routine, or the value of one of those strings.

```
ArgData = '0WHOLE>0 oENO'  
if #Bif_ArgExists.2 then ArgData = 'rWHOLE>0 rENO'  
call CheckArgs ArgData  
  
if \#Bif_ArgExists.1 then return #Arg.#Level.0  
  
ArgNum=#Bif Arg.1  
  
if \#Bif_ArgExists.2 then return #Arg.#Level.ArgNum  
  
if #Bif_Arg.2 == '00' then return \#ArgExists.#Level.ArgNum  
else return #ArgExists.#Level .ArgNum
```

### 12.5.3 CONDITION

CONDITION returns information associated with the current condition.

```
call CheckArgs 'oCDEIS'  
  
/* Values are null if this is not following a condition. */  
if #Condition.#Level == '' then do  
#ConditionDescription.#Level = ''  
#ConditionExtra.#Level = ''  
#ConditionInstruction.#Level  
end  
  
Option=#Bif Arg.1  
  
if Option=='C' then return #Condition.#Level  
  
if Option=='D' then return #ConditionDescription. #Level  
if Option=='E' then return #ConditionExtra.#Level  
  
if Option=='I' then return #ConditionInstruction. #Level  
/* State is the current state. */  
  
if #Condition.#Level = '' then return ""  
return #Enabling.#Condition.#Level
```

### 12.5.4 DIGITS

DIGITS returns the current setting of NUMERIC DIGITS. call CheckArgs ''

```
return #Digits.#Level
```

### 12.5.5 ERRORTXT

ERRORTXT returns the unexpanded text of the message which is identified by the first argument. A second argument of 'S' selects the standard English text, otherwise the text

may be translated to another national language. This translation is not shown in the code below.

```
call CheckArgs 'r0_90 oSN'

msgcode = #Bif Arg.1

if #Bif_ ArgExists.2 then Option
else Option

return #ErrorText .msgcode
```

### 12.5.6 FORM

FORM returns the current setting of NUMERIC FORM.

```
#Bif_Arg.2
tint

call CheckArgs ''

return #Form.#Level
```

### 12.5.7 FUZZ

FUZZ returns the current setting of NUMERIC FUZZ.

```
call CheckArgs ''

return #Fuzz.#Level
```

### 12.5.8 SOURCELINE

If there is no argument, SOURCELINE returns the number of lines in the program, or '0' if the source program is not being shown on this execution. If there is an argument it specifies the number of the line of the source program to be returned.

```
call CheckArgs 'oWHOLE>0'

if \#Bif_ArgExists.1 then return #SourceLine.0
Num = #Bif_Arg.1
if Num > #SourceLine.00 then
call Raise 40.34, Num, #SourceLine.0
return #SourceLine.Num
```

### 12.5.9 TRACE

TRACE returns the trace setting currently in effect, and optionally alters the setting.

```
#TraceInstruction = '1'
value = ''
if #Contains(trace, valueexp) then Value = #Evaluate(valueexp,
expression)
```

```

if #Contains (trace, taken constant) then Value = #Instance (trace,
    taken constant)
if datatype(Value) == 'NUM' & \datatype(Value, 'W') then
    call #Raise 'SYNTAX', 26.7, Value
if datatype(Value, 'W') then do
    /* Numbers are used for skipping. */
    if Value >= 0 then #InhibitPauses = Value
        else #InhibitTrace = -Value
    end
else do
    if length(Value) = 0 then do
        #Interactive.#Level = '0'
        Value = 'N'
    end
    /* Each question mark toggles the interacting. */
    do while left(Value, 1) == '?'
        #Interactive.#Level = \#Interactive.#Level
        Value = substr(Value, 2)
    end
    if length(Value) \= 0 then do
        Value = translate( left(Value, 1) )
        if verify(Value, 'ACEFILNOR') > 0 then
            call #Raise 'SYNTAX', 24.1, Value
            if Value == '00' then #Interactive.#Level = '0'
        end
    end
    #Tracing.#Level = Value
end

```

#### 10.4 Conversion built-in functions

Conversions between Binary form, Decimal form, and hexadecimal form do not depend on the encoding (see nnn) of the character data.

Conversion to Coded form gives a result which depends on the encoding. Depending on the encoding, the result may be a string that does not represent any sequence of characters.

##### 12.5.10 B2X

B2X performs binary to hexadecimal conversion.

```
call CheckArgs 'rBIN'
```

```
String = space (#Bif Arg.1, 0)
return ReRadix(String, 2, 16)
```

##### 12.5.11 BITAND

The functions BITAND, BITOR and BITXOR operate on encoded character data. Each binary digit from the encoding of the first argument is processed in conjunction with the corresponding bit from the second argument.

```
call CheckArgs 'rANY oANY oPAD'
```

```
String1 = #Bif_ Arg.1
```

```

if #Bif ArgExists.2 then String2
#Bif Arg.2
else String2 rr

/* Presence of a pad implies character strings. */
if #Bif_ArgExists.3 then
if length(String1) > length(String2) then
String2=left (String2,length(String1),#Bif_Arg.3)
else
String1=left(String1,length(String2),#Bif_Arg.3)

/* Change to manifest bit representation. */
#Response=Config C2B(String1)
String1=#Outcome
#Response=Config C2B(String2)
String2=#Outcome
/* Exchange if necessary to make shorter second. */
if length(String1)<length(String2) then do

t=String1
String1=String2
String2=t

end

/* Operate on common length of those bit strings. */
r=''
do j=1 to length (String2)
b1=substr (String1,j,1)
b2=substr (String2,j,1)

select
when #Bif='BITAND' then
b1=b1&b2
when #Bif='BITOR' then
b1=b1|b2

115
when #Bif='BITXOR' then
b1=b1&&b2
end
r=r||b1
end j
rer || right (String1, length (String1) -length(String2) )

/* Convert back to encoded characters. */
return x2c (b2x(r))

```

## 12.5.12 BITOR

See nnn

### 12.5.13 BITXOR

See nnn

### 12.5.14 C2D

C2D performs coded to decimal conversion.

```
call CheckArgs 'rANY oWHOLE>=0'
if length(#Bif Arg.1)=0 then return 0

if #Bif_ArgExists.2 then do
/* Size specified */
Size = #Bif_Arg.2
if Size = 0 then return 0
/* Pad will normally be zeros */
t=right (#Bif Arg.1,Size,left (xrange(),1))
/* Convert to manifest bit */
call Config C2B t
/* And then to signed decimal. */
Sign = Left (#Outcome,1)
#Outcome = substr(#Outcome, 2)
t=ReRadix (#Outcome, 2,10)
/* Sign indicates 2s-complement. */
if Sign then t=t-2**length(#Outcome)
if abs(t) > 10 ** #Digits.#Level - 1 then call Raise 40.35, t
return t
end
/* Size not specified. */
call Config C2B #Bif_Arg.1
t = ReRadix(#Outcome, 2,10)
if t > 10 ** #Digits.#Level - 1 then call Raise 40.35, t
return t
```

10.4.6 C2X C2X performs coded to hexadecimal conversion.

```
call CheckArgs 'rANY'
if length(#Bif Arg.1) = 0 then return ''

call Config C2B #Bif_Arg.1
return ReRadix (#Outcome,2,16)
```

### 12.5.15 D2C

D2C performs decimal to coded conversion.

```
'rWHOLENUM>=0'!
'rWHOLENUM rWHOLE>=0'

if \#Bif_ArgExists.2 then ArgData
else ArgData
call CheckArgs ArgData

/* Convert to manifest binary */
Subject = abs(#Bif Arg.1)
r = ReRadix(Subject,10,2)
```

```

/* Make length a multiple of 8, as required for Config B2C */
Length = length(r)
do while Length//8 \= 0
Length = Length+1
end
r= right(r,Length,'0')

/* 2s-complement for negatives. */
if #Bif_Arg.1<0 then do
Subject = 2**length(r)-Subject
r = ReRadix(Subject,10,2)
end
/* Convert to characters */
#Response = Config B2C(r)
Output = #Outcome
if \#Bif_ArgExists.2 then return Output

/* Adjust the length with appropriate characters. */
if #Bif_Arg.1>=0 then return right (Output, #Bif_Arg.2,left(xrange(
,1))
else return right (Output, #Bif Arg.2,right (xrange(),1))

```

#### 12.5.16 D2X

D2X performs decimal to hexadecimal conversion.

```

if \#Bif_ArgExists.2 then ArgData = 'rWHOLENUM>=0'
else ArgData = 'rWHOLENUM rWHOLE>=0'

call CheckArgs ArgData

/* Convert to manifest hexadecimal */
Subject = abs(#Bif Arg.1 )
r = ReRadix(Subject,10,16)
/* Twos-complement for negatives */
if #Bif_Arg.1<0 then do
Subject = 16**length(r) -Subject
r = ReRadix(Subject,10,16)
end
if \#Bif_ArgExists.2 then return r
/* Adjust the length with appropriate characters. */
if #Bif_ Arg.1>=0 then return right(r,#Bif Arg.2,'0')
else return right(r,#Bif Arg.2,'F')

```

#### 12.5.17 X2B

X2B performs hexadecimal to binary conversion.

```

call CheckArgs 'rHEX'

Subject = #Bif Arg.1

if Subject == '' then return ''

/* Blanks were checked by CheckArgs, here they are ignored. */

```

```

Subject = space (Subject, 0)
return ReRadix(translate (Subject) ,16,2)

```

### 12.5.18 X2C

X2C performs hexadecimal to coded character conversion.

```

call CheckArgs 'rHEX'
Subject = #Bif Arg.1
if Subject == '' then return ''
Subject = space (Subject, 0)
/* Convert to manifest binary */
r = ReRadix(translate (Subject) ,16,2)
/* Convert to character */
Length = 8*( (length (Subject) +1) %2)
#Response = Config B2C(right(r,Length,'0'))
return #Outcome

```

### 12.5.19 X2D

X2D performs hexadecimal to decimal conversion.

```

call CheckArgs 'rHEX 0WHOLE>=0'
Subject = #Bif Arg.1
if Subject == '' then return '0'
Subject = translate (space (Subject,0))
if #Bif ArgExists.2 then
Subject = right (Subject, #Bif Arg.2, '0')
if Subject == '' then return '0'
/* Note the sign */
if #Bif ArgExists.2 then SignBit
else SignBit
/* Convert to decimal */
r = ReRadix(Subject,16,10)
/* Twos-complement */
if SignBit then r = 2**(4*#Bif Arg.2) - r
if abs(r)>10 ** #Digits.#Level - 1 then call Raise 40.35, t
return r
left (x2b (Subject) ,1)
ror

```

## 12.6 Input/Output built-in functions

The configuration shall provide the ability to access streams. Streams are identified by character string identifiers and provide for the reading and writing of data. They shall support the concepts of characters, lines, and positioning. The input/output built-in functions interact with one another, and they make use of Config\_ functions, see nnn. When the operations are successful the following characteristics shall be exhibited:

- The CHARIN/CHAROUT functions are insensitive to the lengths of the arguments. The data written to a stream by CHAROUT can be read by a different number of CHARINs.
- The CHARIN/CHAROUT functions are reflective, that is, the concatenation of the data read from a persistent stream by CHARIN (after positioning to 1, while CHARS(Stream)>0), will be the same as the concatenation of the data put by CHAROUT.
- All characters can be used as CHARIN/CHAROUT data.
- The CHARS(Stream, 'N') function will return zero only when a subsequent read (without positioning) is guaranteed to raise the NOTREADY condition.
- The LINEIN/LINEOUT functions are sensitive to the length of the arguments, that is, the length of a line written by LINEOUT is the same as the length of the string returned by successful LINEIN of the line.
- Some characters, call them line-banned characters, cannot reliably be used as data for LINEIN/LINEOUT. If these are not used, LINEIN/LINEOUT is reflective. If they are used, the result is not defined. The set of characters which are line-barred is a property of the configuration.
- The LINES(Stream, 'N') function will return zero only when a subsequent LINEIN (without positioning) is guaranteed to raise the NOTREADY condition.
- When a persistent stream is repositioned and written to with CHAROUT, the previously written data is not lost, except for the data overwritten by this latest CHAROUT.
- When a persistent stream is repositioned and written to with LINEOUT, the previously written data is not lost, except for the data overwritten by this latest LINEOUT, which may leave lines partially overwritten.

### 12.6.1 CHARIN

CHARIN returns a string read from the stream named by the first argument.

```
call CheckArgs 'oSTREAM o0WHOLE>0 o0WHOLE>=0'

if #Bif_ArgExists.1 then Stream
else Stream
#StreamState.Stream = ''
/* Argument 2 is positioning. */
if #Bif_ArgExists.2 then do
#Response = Config Stream Position(Stream, 'CHARIN', #Bif Arg.2)

#Bif Arg.1
```

```

if left(#Response, 1) == 'R' then call Raise 40.41, 2, #Bif_ Arg.2
if left(#Response, 1) == 'T' then call Raise 40.42, Stream
end

/* Argument 3 is how many. */
if #Bif_ArgExists.3 then Count
else Count
if Count = 0 then do
call Config Stream Charin Stream, 'NULL' /* "Touch" the stream */
return '!'
end
/* The unit may be eight bits (as characters) or one character. */
call Config Stream Query Stream

#Bif Arg.3
1

Mode = #Outcome

do until Count = 0

#Response = Config Stream Charin(Stream, 'CHARIN')

if left(#Response, 1) \== 'N' then do
if left (#Response, 1) == 'E' then #StreamState.Stream = 'ERROR'

call #Raise 'NOTREADY', Stream, substr(#Response, 2)

return Residue
end
Residue = Residue - 1
end
return 0

```

### 12.6.3 CHARS

CHARS indicates whether there are characters remaining in the named stream. Optionally, it returns a

count of the characters remaining and immediately available.

```
call CheckArgs 'oSTREAM oCN'
```

```
if #Bif_ArgExists.1 then Stream = #Bif_Arg.1
else Stream = ''
```

```

if #Bif_ArgExists.2 then Option = #Bif Arg.2
else Option = 'N'

call Config Stream Count Stream, 'CHARS', Option
return #Outcome

```

#### 12.6.4 LINEIN

LINEIN reads a line from the stream named by the first argument, unless the third argument is Zero.

```

call CheckArgs 'oSTREAM o0WHOLE>0 o0WHOLE>=0'

if #Bif_ArgExists.1 then Stream
else Stream
#StreamState.Stream = ''
if #Bif_ArgExists.2 then do
#Response = Config Stream Position(Stream, 'LINEIN', #Bif Arg2)
if left (#Response, 1) 'T' then call Raise 40.42, Stream
if left (#Response, 1) 'R' then call Raise 40.41, 2, #Bif_ Arg.2
end
if #Bif_ArgExists.3 then Count #Bif Arg.3
else Count 1

if Maximum-Minimum<0 then
  call Raise 40.33, Minimum, Maximum

if #Bif_ArgExists.3 then call Config Random Seed #Bif_Arg.3
call Config Random Next Minimum, Maximum
return #Outcome
```

### 12.7.4 SYMBOL

The function SYMBOL takes one argument, which is evaluated. Let String be the value of that argument. If Config\_Length(String) returns an indicator 'E' then the SYNTAX condition 23.1 shall be raised. Otherwise, if the syntactic recognition described in section nnn would not recognize String as a symbol then the result of the function SYMBOL is 'BAD'.

If String would be recognized as a symbol the result of the function SYMBOL depends on the outcome of accessing the value of that symbol, see nnn. If the final use of Var\_Value leaves the indicator with value 'D' then the result of the function SYMBOL is 'LIT', otherwise 'VAR'.

## 12.7.5 TIME

TIME with less than two arguments returns the local time within the day, or an elapsed time. Otherwise it converts the second argument (which has a format given by the third argument) to the format specified by the first argument.

```
call CheckArgs 'oCEHLMNORS oANY oCHLMNS'
/* If the third argument is given then the second is mandatory. */

return Value

```

## Built-in classes

---

### 13.1 Notation

The built-in classes are defined mainly through code. The code refers to state variables. This is solely a notation used in this standard.

### 13.2 Object, class and method

These objects provide the basis for class structure.

#### 13.2.1 The object class

```
::class object
```

```
::method new class
```

Returns a new instance of the receiver class.

```
call Config ObjectNew
return #Outcome
```

```
::method '=='
```

*'==' with no argument gives a hash value in OOI.*

```
call Config ObjectCompare #Receiver, #Arg.1
if #Outcome == 'equal' then return '1'
else return '0'
```

```
::method '<>'
use arg a
return \self==a
```

```
::method '><'
forward message '<>'
```

```
::method '='
forward message '=='
```

```
::method '\='
forward message '<>'
```

```
::method '\=='
forward message '<>'
```

```
::method copy
```

Returns a copy of the receiver object. The copied object has the same methods as the receiver object and an equivalent set of object variables, with the same values.

```
call Config ObjectCopy #Receiver
return #Outcome
```

*Since we have var\_empty we could save a primitive by rendering 'new' as 'copy' plus 'empty'.*

```
::method defaultname
```

Returns a short human-readable string representation for the object.

```
call var_value #Receiver, '#Human', '0'
return #Outcome
```

*This field would have been filled in at 'NEW' time.*

```
::method 'OBJECTNAMES'          /* rSTRING */
```

Sets the receiver object's name to the specified string.

```
Var_Set(#Pool, 'SIGL', '0', #LineNumber)
var_Set(0, '.SIGL', '0', #LineNumber)
```

*Initialized to #Human? Or ObjectName does forwarding until assigned to?*

```
::method objectname
```

Returns the receiver object's name (which the OBJECTNAME= method sets).

```
call var_value #Receiver, #ObjectName, '0'
return #Outcome
```

```
::method string
```

Returns a human-readable string representation for the object.

```
::class method
```

```
::method new class      /* rSTRING rSOURCE */
```

Returns the class object that received the message that created the object.

```
call var value #Receiver, #IsA, '0'
return #Outcome
```

```
::method setmethod      /* rSTRING oSTRING/METHOD/ARRAY */
```

Adds a method to the receiver object's collection of object methods.

*Is 'object methods' what is intended; you add to a class without adding to its instance methods? Yes.*

```
if #ArgExists.2 then m = Arg.2
                    else m = .NIL
call set_var #Receiver, 'METHODS.'#Arg.1, '1', m
return
```

```
::method hasmethod      /* rSTRING */
```

Returns 1 (true) if the receiver object has a method with the specified name (translated to uppercase); otherwise, returns 0 (false).

*This presumably means inherited as well as SETMETHOD ones. What about ones set to .NIL?  
Need to use the same search as for sending.*

```
::method unsetmethod private
```

Removes a method from the receiver object's collection of object methods.

*Use var\_drop*

*Private means Receiver = Self check.*

```
::method request          /* rSTRING */
```

Returns an object of the specified class, or the NIL object if the request cannot be satisfied.

```
t = 'MAKE'#Arg.1
if \#Receiver~hasmethod(t) then return .NIL
forward message(t) array ()
```

```
::method run private /* rMETHOD Ugh keyoptions */
```

Runs the specified method. The method has access to the object variables of the receiver object, just as if the receiver object had defined the method by using SETMETHOD.

```
::method startat          Undocumented?
::method start            /* rMESSAGE oArglist */
```

Returns a message object and sends it a START message to start concurrent processing.

```
::method init
```

Performs any required object initialization.

### 13.2.2 The class class

```
::class class
```

*Lots of these methods are both class and instance. I don't know whether to list them twice.*

```
::method new class        /* oARGLIST */
```

Returns a new instance of the receiver class, whose object methods are the instance methods of the class. This method initializes a new instance by running its INIT methods.

```
::method subclass class
```

Returns a new subclass of the receiver class.

```
::method subclasses class
```

Returns the immediate subclasses of the receiver class in the form of a single-index array of the required size.

```
::method define class /* rSTRING oMETHOD */
```

Incorporates the method object in the receiver class's collection of instance methods. The method name is translated to upper case.

```
::method delete
```

Removes the receiver class's definition for the method name specified.

*Builtin classes cannot be altered.*

```
::method method class /* rSTRING */
```

Returns the method object for the receiver class's definition for the method name given.  
*Do we have to keep saying "method object" as opposed to "method" because "method name" exists?*

```
::method querymixinclass
```

Returns 1 (true) if the class is a mixin class or 0 (false) otherwise.

```
::method mixinclass class /* 3 of em */
```

Returns a new mixin subclass of the receiver class.

```
::method inherit class /* rCLASS oCLASS */
```

Causes the receiver class to inherit the instance and class methods of the class object specified. The optional class is a class object that specifies the position of the new superclass in the list of superclasses.

```
::method uninherit class /* rCLASSOBJ */
```

Nullifies the effect of any previous INHERIT message sent to the receiver for the class specified.

```
::method enhanced class /* rCOLLECTION oArgs */
```

Returns an enhanced new instance of the receiver class, with object methods that are the instance methods of the class enhanced by the methods in the specified collection of methods.

```
::method baseclass class
```

Returns the base class associated with the class. If the class is a mixin class, the base class is the first superclass that is not also a mixin class. If the class is not a mixin class, then the base class is the class receiving the BASECLASS message.

```
::method superclasses class
```

Returns the immediate superclasses of the receiver class in the form of a single-index array of the required size.

```
::method id class
```

Returns a string that is the class identity (instance SUBCLASS and MIXINCLASS methods.)

```
::method metaclass class
```

Returns the receiver class's default metaclass.

```
::method methods class /* oCLASSOBJECT */
```

Returns a supplier object for all the instance methods of the receiver class and its superclasses, if no argument is specified.

### 13.2.3 The method class

```
::class method
```

```
::method new class /* rSTRING rSOURCE */
```

Returns a new instance of method class, which is an executable representation of the code contained in the source.

Specifies that a method is a private method.

```
::method setsecuritymanager
```

Reverses any previous SETUNGUARDED messages, restoring the receiver to the default guarded status.

Lets an object run a method even when another method is active on the same object. If a method object does not receive a SETUNGUARDED message, it requires exclusive use of its object variable pool.

Returns the method source code as a single index array of source lines.

```
::method setinterface
```

The string class provides conventional strings and numbers.

```
::class string
```

```
::method '\'
```

```
::method '-'  
::method '-'  
    use arg a  
    return \a
```

```
:method '+'
:method '**'
:method '*'
:method '%'
:method '/'
:method '//'
:method '|'
:method '||'
:method '<>'
:method '><'
```

```

:method '='
:method '\='
:method '\=='
:method '=='
:method '<'
:method '>'
:method '>='
:method '/<'
:method '<='
:method '/>'
:method '<<'
:method '>>'
:method '>>='
:method '/>>'
:method '<<='
:method '\<<'
:method '&&'
:method '&'
:method abbrev

:method centre
:method center
:method changestr
:method compare
:method copies
:method counstr
:method datatype
:method delstr
:method delword
:method insert
:method lastpos
:method left
:method length
:method overlay
:method pos
:method reverse
:method right
:method space
:method strip
:method substr
:method subword
:method translate
:method verify
:method word
:method wordindex
:method wordlength
:method wordpos
:method words
:method abs
:method format
:method max
:method min
:method sign
:method trunc
:method B2X
:method bitand
:method bitor

```

```
:method bitxor
:method C2D
:method C2X
:method D2X
::method string

::method makestring
```

### 13.2.5 The array class

The main features of a single dimension array are provided by the configuration. This section defines further methods and multi-dimensional arrays.

*To be done. Dimensionality set at first use. Count commas, not classic arg().*

```
::class array

::method new class      /* 0 or more WHOLE>=0 */
```

Returns a new empty array.

```
::method of class      /* 0 or more ANY */
```

Returns a newly created single-index array containing the specified value objects.

```
::method put           /* rANY one or more WHOLE>0 */
```

Makes the object value a member item of the array and associates it with the specified index or indexes.

```
::method ' []='        /* 1 or more WHOLE>0 */
```

This method is the same as the PUT method.

```
::method at            /* 1 or more WHOLE>0 */
```

Returns the item associated with the specified index or indexes.

```
::method ' []'         /* 1 or more WHOLE>0 */
```

Returns the same value as the AT method.

```
::method remove        /* 1 or more WHOLE>0 */
```

Returns and removes the member item with the specified index or indexes from the array.

```
::method hasindex      /* 1 or more WHOLE>0 */
```

Returns 1 (true) if the array contains an item associated with the specified index or indexes. Returns 0 (false) otherwise.

```
::method items         /* (None) */
```

Returns the number of items in the collection.

```
::method dimension     /* oWHOLE>0 */
```

Returns the current size (upper bound) of dimension specified (a positive whole number). If you omit the argument this method returns the dimensionality (number of dimensions) of the array.

`::method size` `/* (None) */`

Returns the number of items that can be placed in the array before it needs to be extended.

`::method first` `/* (None) */`

Returns the index of the first item in the array, or the NIL object if the array is empty.

`::method last` `/* (None) */`

Returns the index of the last item in the array, or the NIL object if the array is empty.

`::method next` `/* rWHOLE>0 */`

Returns the index of the item that follows the array item having the specified index or returns the NIL object if the item having that index is last in the array.

`::method previous` `/* rWHOLE>0 */`

Returns the index of the item that precedes the array item having index index or the NIL object if the item having that index is first in the array.

`::method makearray` `/* (None) */`

Returns a single-index array with the same number of items as the receiver object. Any index with no associated item is omitted from the new array.

Returns a new array (of the same class as the receiver) containing selected items from the receiver array. The first item in the new array is the item corresponding to index start (the first argument) in the receiver array.

`::method supplier` `/* (None) */`

Returns a supplier object for the collection.

`::method section` `/* rWHOLE>00 oWHOLE>=0 */`

### 13.2.6 The supplier class

A supplier object enumerates the items a collection contained at the time of the supplier's creation.

`::class supplier`

`::method new class` `/* rANYARRAY rINDEXARRAY */`

Returns a new supplier object.

`::method index`

Returns the index of the current item in the collection.

`::method next`

Moves to the next item in the collection.

`::method item`

Returns the current item in the collection.

`::method available`

Returns 1 (true) if an item is available from the supplier (that is, if the ITEM method would return a value). Returns 0 (false) otherwise.

### 13.2.7 The message class

`::class message`

`::method init class       /* Ugh */`

Initializes the message object for sending.....

`::method completed`

Returns 1 if the message object has completed its message; returns 0 otherwise.

`::method notify           /* rMESSAGE */`

Requests notification about the completion of processing for the message SEND or START sends.

`::method start           /* oANY */`

Sends the message for processing concurrently with continued processing of the sender.

`::method send           /* oANY */`

Returns the result (if any) of sending the message.

`::method result`

Returns the result of the message SEND or START sends.

## Provided classes

---

(Informative)

### 14.1 Notation

The provided classes are defined mainly through code. ## The Collection Classes

#### 14.1.1 Collection Class Routines

These routines are used in the definition of the collection classes

```
::routine CommonXor
/* Returns a new collection that contains all items from self and
the argument except that all indexes that appear in both collections
are removed. */
/* When the target is a bag, there may be an index in the bag that is
duplicated and the same value as an index in the argument. Should one
copy of the index survive in the bag? */
v=1
if (arg(1)~class==.Set & arg(2)~class==.Bag) then v=2
if (arg(1)~class==.Table & arg(2)~class==.Bag) then v=2
if (arg(1)~class==.Table & arg(2)~class==.Relation) then v=2
if (arg(1)~class==.Directory & arg(2)~class==.Bag) then v=2
if (arg(1)~class==.Directory & arg(2)~class==.Relation) then v=2
/* This version it does: */
if v=1 then do
  This = arg(1) /* self of caller */
  r=This~class~new
  ab=MayEnBag (arg (2) )
  ss=This~supplier
  do while ss~available
    r[ss~index] =ss~item
    ss~next
  end
  cs=ab~supplier
  do while cs~available
    if r~hasindex(cs~index) then r~remove (cs~index)
    else r[cs~index] =cs~item
    cs~next
  end
  return r
end

/* But following matches practice on Set~XOR(bag) etc. */
```

```

This = arg(1) /* self of caller */
r=This~class~new
ab=MayEnBag (arg (2) )
ss=This~supplier
do while ss~available
  if \ab~hasindex(ss~index) then r[ss~index] =ss~item
  ss~next
end
cs=ab~supplier
do while cs~available
  if \This~hasindex(cs~index) then r[cs~index] =cs~item
  cs~next
end
return r

::routine CommonIntersect
/* Returns a new collection of the same class as SELF that
contains the items from SELF that have indexes also in the
argument. */
/* Actually an index in SELF can only be 'matched' with one in the
argument once. Hence copy and removal. */
This = arg(1) /* self of caller */
w= .Bag~new
sc=This~supplier
do while sc~available
  w[sc~index] =sc~index
  sc~next
end
r=This~class~new
cs=MayEnBag(arg(2))~supplier
do while cs~available
  i=cs~index
  if w~hasindex(i) then do
    r[i]=This[i]
    w~remove(i)
  end
  cs~next
end
return r

::routine CommonUnion
/* Returns a new collection of the same class as SELF that
contains all the items from SELF and items from the
argument that have an index not in the first. */
/* Best to add them all. By adding non-receiver first we ensure that
receiver takes priority when same indexes. */
This = arg(1) /* self of caller */
r=This~class~new
cs=MayEnBag(arg(2))~supplier
do while cs~available
  r[cs~index] =cs~item
  cs~next
end
cs=This~supplier
do while cs~available
  r[cs~index] =cs~item
  cs~next
end

```

```

        end
    return r

::routine CommonDifference
/* Returns a new collection containing only those index-item pairs
   from the
   SELF whose indexes the other collection does not contain. */
    This = arg(1) /* self of caller */
    r=This~class~new
    cs=This~supplier
    do while cs~available
        r[cs~index] =cs~item
        es~next
    end
    cs=MayEnBag(arg(2))~supplier
    do while cs~available
        r~remove(cs~index)
        cs~next
    end
    return r

::routine MayEnBag
/* For List and Queue the indexes are dropped. */
    r~arg(1)
    if r-clags == .List | r-class == .Queue then r=EnBag(r)
    return r

::routine EnBag
    r=.Bag~new
    s=arg(1)~supplier
    do while s~available
        if arg(1)~class == .List | arg(1)~class == .Queue then
            r[s~item] =s~item
        else
/* This case is when the receiver is a Bag. */
            r[s~index] =s~index
            s~next
        end
    end
    return r

```

### 14.1.2 The collection class

```

::class 'Collection'

```

```

INIT

```

```

::method init
    expose a
/* A collection is modelled as using 3 slots in an array for each
   element.
   The first slot holds the item, the second the index, and the third is
   used by particular types of collection. This order of slots is
   arbitrary,
   chosen to match order of arguments for PUT and SUPPLIER~NEW. */
/* The first set of 3 slots is reserved for other purposes, to avoid

```

```

having separate variables which the subclassing would need to access.
*/
a=.array~new
a[1] /*ItemsCount*/=0
a[2]/*Unique*/=0
return self

```

#### EXPOSED

```

::method exposed private
  expose a
/* This method allows subclasses to get at the implementation of
  Collection. */
  return a

```

#### FINDINDEX

```

::method findindex private
  expose a
/* Returns array index if the collection contains any item associated
  with the
  index specified or returns 0 otherwise. */
  do j=4 by 3 to 1+3*a[1]/*ItemsCount*/
    if a[j+1]==arg(1) then return j
  end j
  return 0

```

#### AT

```

::method at /* rANY */
  expose a
/* Returns the item associated with the specified index. */
  j=self~findindex(arg(1))
  if j=0 then return .nil
  return a[j]

```

[]

```

::method '['
/* Synonym for the AT method. */
  forward message 'AT'

```

#### PUT

```

::method put /* rANY rAny */
  expose a
  use arg item, index
/* Replaces any existing item associated with the specified index
  with the new
  item. Otherwise adds the item-index pair. */
  j=self~findindex(index)
  if j>0 then do
    a[j]=item
    return
  end
  a[1]/*ItemsCount*/=a[1] /*ItemsCount*/+1
  j=1+3*a[1]/*ItemsCount*/
  a[j]=item

```

```

a[j+1]=index
a[j+2]=0
return /* Error 91 in 00I if context requiring result. */

[]=

::method '[]='
/* Synonym for the PUT method. */
forward message 'PUT'

HASINDEX

::method hasindex /* rANY */
/* Returns 1 (true) if the collection contains any item associated
with the
index specified or returns 0 (false) otherwise. */
return self~findindex(arg(1))>0

ITEMS

::method items
expose a
/* Returns the number of items in the collection. */
return a[1]/*ItemsCount*/

REMOVE

::method remove /* rANY */
expose a
/* Returns and removes from a collection the member item with the
specified
index. */
j=self~findindex(arg(1))
if j=0 then return .nil
r=a[j]
self~removeit(j)
return r

REMOVEIT

::method removeit private
expose a
use arg j
/* Remove relevant slots from the array, with compaction. */
do j=j+3 by 3 to 1+3*a[1]/*ItemsCount*/
a[j-3]=a[j];a[j-2]=a[j+1];a[j]=a[j+2]
end j
a[1]/*ItemsCount*/=a[1]/*ItemsCount*/-1
return

MAKEARRAY

::method makearray
expose a
/* Returns a single-index array containing the receiver list items.
*/
r=.array~new /* To build result in. */
do j=4 by 3 to 1+3*a[1]/*ItemsCount*/

```

```

        r[r~dimension(1)+1]=a[j]
    end j
    return r

```

#### MAKEARRAYX

```

::method makearrayx private
    expose a
/* Returns a single-index array containing the receiver index items.
*/
    r= .array~new          /* To build result in. */
    do j=4 by 3 to 1+3*a[1]/*ItemsCount*/
        r[r~dimension(1)+1]=a[j+1]
    end j
    return r

```

#### SUPPLIER

```

::method supplier
    expose a
/* Returns a supplier object for the list. */
    return .supplier~new(self~makearray:.collection, self~makearrayx)

```

#### 14.1.3 Class list

```

::class 'List' subclass Collection

```

##### PUT

```

::method put          /* rANY rANY */
    use arg item, index
    a=self~exposed
/* PUT for a List must not be an insertion. */
    j=self~findindex (index)
    if j=0 then call Raise 'Syntax',93.918
    a[j]=item
    return

```

##### OF

```

::method of class      /* 1 or more oANY  Are they omissible? Not in
    IOO */
/* Returns a newly created list containing the specified value
    objects in the
order specified. */
    r= self ~ new
    do j = 1 to arg()
        r ~ insert (arg(j))
    end j
    return r

```

##### INSERT

```

::method insert        /* rANY oANY */
    use arg item, index
    a=self~exposed
/* Returns a list-supplied index for a new item, of specified value,
    which is

```

```

added to the list. The new item follows the existing item with the
specified
index in the list ordering. */
/* Establish the index of what preceeds the new element. */
/* If there was no index given, the new item becomes the last on list
. */
/* .nil argument means first */

/* X3J18 Rexx Language Standard proposal for the Set-like operations
   on the
Collection classes */

/* Tn the same way that the first standard uses BIFs which are
   defined using
other BIFs and ultimately the arithmetic and character operators, the
second
standard can define classes using other classes and some fundamental
basis.

This program gives the definition of some other classes, in a form
which
(when thoroughly developed) might be part of the second standard. It
also
has a testing mechanism, which will not be part of a standard.

This particular program is implementing collections on top of array.

## 14.2 The stream class

The stream class provides input/output on external streams.

```

::class stream

::method init          /* rString */

```

Initializes a stream object for a stream named name, but does not open the stream.

```

::method query        /* keywords */

```

*There is also QUERY as command with method COMMAND.*

Used with options, the QUERY method returns specific information about a stream.

```

::method charin
::method charout
::method chars
::method linein
::method lineout
::method lines
::method qualify

```

::method command           /\* rString \*/

Returns a string after performing the specified stream command.

::method open

*There is also OPEN as command with method COMMAND.*

Opens the stream to which you send the message and returns “READY:”.

*Committee dropping OPEN POSITION QUERY SEEK as methods in favour of command use.*

::method state

Returns a string that indicates the current state of the specified stream.

::method say

::method uninit

::method position       /\* Ugh \*/

POSITION is a synonym for SEEK.

::method seek           /\* Ugh \*/

Sets the read or write position a specified number (offset) within a persistent stream.

::method flush

Returns “READY:”. Forces any data currently buffered for writing to be written to the stream receiving the message.

*There is also FLUSH as command with method COMMAND.*

*Committee dropping FLUSH.*

::method close

Closes the stream that receives the message.

*There is also CLOSE as command with method COMMAND.*

*Semantics are ‘seen by other thread’.*

::method string

::method makearray       /\* rCHARLINE \*/

Returns a fixed array that contains the data from the stream in line or character format, starting from the current read position.

::method supplier

Returns a supplier object for the stream.

::method description

::method arrayin       /\* rCHARLINE \*/

*Mixed case value works on OOI.*

*Committee dropping Arrayin & Arrayout. Arrayin == MakeArray*

Returns a fixed array that contains the data from the stream in line or character format, starting from the current read position.

```
::method arrayout      /* rARRAY rCHARLINE */
```

Returns a stream object that contains the data from array.

### 14.3 The alarm class

```
::class alarm
```

```
::method init /* Time, Msg */
```

Sets up an alarm for a future time atime.

```
::method cancel
```

Cancels the pending alarm request represented by the receiver. This method takes no action if the specified time has already been reached.

### 14.4 The monitor class

The Monitor class forwards messages to a destination object.

```
.local ['OUTPUT'] = .monitor~new(.output)
```

```
::class monitor
```

#### 14.4.1 INIT

Initializes the newly created monitor object.

```
::method init      /* oDESTINATION */  
  expose Destination  
  Destination = .queue~new  
  if arg(1, 'E') then Destination~push(arg(1))  
  return
```

#### 14.4.2 CURRENT

Returns the current destination object.

```
::method current  
  expose Destination  
  return Destination [1]
```

### 14.4.3 DESTINATION

Returns a new destination object.

```
::method destination /* oDESTINATION */  
  expose Destination  
  if arg(1,'E') then Destination~push (arg(1))  
    else Destination~pull  
  return Destination[1]
```

### 14.4.4 UNKNOWN

Reissues or forwards to the current monitor destination all unknown messages sent to a monitor object

```
::method unknown  
  expose Destination
```

*Extra parens needed here in original OREXX syntax*

```
  forward to destination[1] message arg(1) arguments arg(2)  
  return
```

## Rationale

This annex explains some of the decisions made by the committee that drafted this standard, and assists in the understanding of this document. Some of the statements made here are opinions rather than facts. These should be interpreted as if prefixed by “In the opinion of the X3J18 committee...”.

The language described in this standard is, almost entirely, a compatible extension of the language described by the third reference of Annex C, which we call “Classic Rexx”.

The extension allows programs to be written in a less monolithic fashion; “Directives” are introduced to allow one file to contain several executable units and to allow a program to be written as several files. The functional extension centers on the addition of objects. Unlike the individual strings which are the data of Classic Rexx, an object may be composite. The use of identifiers to reference objects is an indirect reference, that is two identifiers may refer to the same object. Classic Rexx avoided any aliasing, even to the extent having by-reference parameters, to promote simple error free programming. In the years since Rexx originated the problems tackled by programmers have become more complex and data structures larger, so that the benefit of simplicity is outweighed by the power of assignment semantics that are not simply copying all the data.

Even with the addition of references Rexx remains a typeless language, in the sense that the programmer need not consider underlying hardware formats such as LONG or FLOAT representations. Object Rexx does have classes, which are the hardware independent analogy to types. The class of an object corresponds to the operations that can be performed upon it.

## Incompatibilities

## The incompatibilities from Classic Rexx are:

Assignment of compound variables, as in `ABC. = PQR.`, is an assignment of references so that `ABC.` subsequently refers to the same object as `PQR.`, as opposed to making the default value of `ABC.` that of `PQR.`. This change was necessary to fit compound variables into the object framework, in particular allowing `USE ARG` to handle compound variables as by-reference parameters. The first reference of Annex B discouraged use of this construct in Classic Rexx programs. “Breakage” of programs due to this incompatibility is rare.

Also something in condition handling that I don’t know the reason for.

### 17.1 Call

The call instruction has been extended to allow for a computed name of the callee. Syntax considerations prevent a similar thing being done for functions.

### 17.2 Concurrency

Meet 17 minutes

### 17.3 Guard

Meet 17 minutes

## To be processed:

*The following decisions are abstracted from minutes. We need to ensure they are covered in the main standard and their rationale appropriately reworded for this annex.*

Aliasing. Assignment is viewed as making the target reference the same object as the source. Hence the object (and changes to it) may be accessed through more than one name. For 'immutable' objects a changed version of an object can only be produced by creating a new object. For compatibility with classic Rexx, strings are immutable objects. Non-strings may or may not be immutable. Note that there is an alternative model in which distinction is made between assignments which copy values and assignments which copy references. This alternative was not chosen; the committee preferred the model in which all data names are naming references (which may be implicitly followed to values).

Arguments 'by-reference'. The introduction of aliasing makes this natural although the detail has simple-versus-general contentions. (Is it necessary for simple strings to be passed by reference. Encapsulation. An object may 'own' some variables and access to those may be limited (so that re-implementation of the object could use different variables without upsetting the usage of the object). Classess. There will be factory' objects capable of creating multiple new objects which have common characteristics about how they can be used.

Inheritance and hierachy. The semantics of a clas may be specified by adding to the semantics of another class. This relation is used to form a tree. We prefer a singly rooted tree, rooted in the class Object' which is built-in to the language. Other classes will also be built-in. Experience with OOM and other languages is that unrestricted inheritance by one class from multiple classes does not work in the way the coder intended (the implementations of the classes do not combine successfully). If multiple inheritance is added to Rexx at all, it will be in the cautious 'MIXIN' flavor of OOI.

Messaging: Executing some labelled code which is associated with objects of a given class is a form of invocation that is sufficiently different from classic Rexx to justify a new syntax construct. The new syntax is `Receiver~MethodName(Arguments)` and implies both a different search for the method to be invoked and a special role for the receiver as opposed to the other arguments of the invocation.

Packaging: In principle a program builder' could be used in developing Rexx programs with many classes and methods, and that builder could hide from the coder the details of how the configuration held the methods. However, rather than define a program builder we are choosing to define a simple method of holding multiple classes & mthods (with specification of their hierarchy) within a single text file. The non-executable dividers in such a file are known as directives. The files are known as packages and a package

may specify (by directive) that it requires another package in order to function correctly. There are questions about when initialization of required packages occurs; we intend to find a solution that does not require the complete graph of requirements to be initialized before other code is executed.

A note on the syntax of directives. When no special token (eg ::) is used to introduce directives the directives are be recognizable by the spelling of the keyword. (CLASS REQUIRES etc.) The purpose of the special token is emphasis of directives rather than implementation ease in “pre-processing” the directives.

Packages in non-Rexx. It is necessary to exploit packages that are not written in Rexx. To invoke their methods it is necessary that the package makes known to the Rexx method search the names of the classes and their methods. To do more than invoke the methods (eg to subclass the the external classes) requires complicated mechanisms and may not be a requirement.

External procedures. To allow Classic internal procedures to be separated into different files with undue change of semantics, the PROCEDURE statement will be permitted as the first statement of a routine which is in a separate file.

Concurrency will be added, that is multiple execution cursors progressing through one program. The mechanism for creating multiple cursors will be the “early reply” where one cursor becomes two; one of two progresses by “falling through” the early reply and the other starts its progress after the site of the current invocation. Multiple cursors carry the risk of execution interleaving in a way which negates the coder’s intentions in writing so that clauses would execute sequentially. The language definition will be tightened to ensure atomicity of string assignment etc. Additionally, a set of rules about allowing two cursors on the same method at the same time will provide a reduction of the risk. Since in many cases the data which have to be maintained consistent will reside in a single object the rules are object-based. In general a cursor on a method executing against a particular object will delay any other cursor from executing methods against that object. This rule provides sensible synchronization without much effort from the programmer but other controls may be provided:

- a) Stronger control, eg only one cursor within the methods of a set of objects.
- b) More detailed control, eg division of a method into sections which allow/disallow other cursors into the section.

Extended Variable Pools. The API for variable pools will need to be extended to reflect the model in which the named content in a pool is always a reference (and the reference is followed when the value of a string is required.) We note that OO! adopts a convention that names starting with ‘!’ (shriek) name objects that are not intended for access by the coder. These objects will not be standardized. Additionally some objects without shriek names are not candidates for standardising, eg .SYSTEM, .KERNEL.

A model is needed for whether changes made to methods are seen by objects created before the changes. Changes that are seen are preferable where a long-lived object is being brought up-to-date. Changes that only apply to future objects are preferable if avoiding failure of what “used to work” is the priority. In view of OOM experience the standard should allow both, on a method by method choice. (eg perhaps a bug fix applied retrospectively but not an enhancement.)

Multiple inheritance. Study of the 'method search' algorithm, see later, shows that this is an "add-on" that could readily be retained or omitted. That argues in principle for retention, since the non-user of multiple inheritance would not suffer from it. On the other hand it adds complexity and can be misused even in the conservative form that OOI has it.

Signature-based method search. This is not in OOI but is in languages such as Java.

Subclassing of imported classes. It is our intention to say that imported classes can be used in all the same ways as builtin classes. Because this may be impractical to implement with some external classes, a conforming language processor will have a list (which may be empty) of external classes it supports. (And hence nothing of the current SOM interface will be part of the standard.)

Persistent objects. It is our belief that support for very-long-running programs is required. It is a moot point whether the .ENVIRONMENT directory is enough.

If persistent objects are to be converted to a form which is platform independent, ("pickling"), there are difficulties in deciding what pointers should be followed and further objects included, as opposed to objects being assumed available on all platforms. This topic is deferred.

Locking across a set of objects. In OOI this can only be done by locking the events serially, which has more risk of deadlock than locking them simultaneously. The decision was made not to add simultaneous locking.

Critical sections. The GUARD mechanism can be used in a critical section' style. Nothing will be added to the definition.

Old objects seeing new changed methods. When bugs in long running programs are fixed, there can be a benefit if old objects see the corrected methods. It seems practical to offer a variation of DEFINE for this - see method lookup discussion.

The committee does not find the current OOI approach to merging 'classic' stems with OO stems satisfactory. It invalidates some existing programs. (A warning about this was put in A8.3.3 of X3.274.) It produces surprises for OO programmers, eg `a==b` after `a=.stem~new; b=.stem~new`. The proposed alternative is to make the presence/absence of a dot at the end of the name determine whether coercion to string is done. The 'classic' meaning of `A.=B.` would be restored but `AA=BB`, `AA==BB` etc. would have their OO meanings. The meaning of `USE ARG` with a dotted name would be defined to allow by reference' passing of a stem. Square brackets could be used with both dotted and undotted names. A further proposal is to note that this leaves few differences between the DIRECTORY class and the non-dotted STEM class so that it might be a further improvement if the DIRECTORY class was extended to the extent that the STEM class was unnecessary.

There is a potential problem which the committee has not fully analysed in the OO! treatment of SAY and streams. OOI has made features (of the STREAM bif) that were configuration determined in X3-274 into OO language methods, and has made SAY a method (undocumented?). Full analysis may show that more of I/O could (& should?) be made standard or may show that some OOI I/O language should not be standardized.

The committee discussed what parts of the OOI implementation were suitable to be defined in a standard. Potentially, all the builtin classes and objects (which are reachable

from `.ENVIRONMENT`) might be standardized. However, names which start with an exclamation mark denote unsuitable things. The committee also thought the following unsuitable:

- Anything specific to SOM.
- `RX_QUEUE`
- `Stream_Supplier`
- Parts of `.LOCAL` other than direct reference to the default streams. There is a naming problem with this. The names in OOI are `STDIN`, `STDOUT` and `STDERR`. We would prefer `INPUT`, `OUTPUT`, and `ERROR` to be consistent with the keywords. OOI has used those names for something else. We will work on the proposal that we use the preferred names and the `MONITOR` class is dropped. (Users who want the monitor function can get it with a few lines of directive.)

The committee feels that OOI over-specifies the index of an item in a `LIST`. In OOI it is a count giving the sequence over time of the insertions in the list. The risk in using numbers is that they may be (wrongly) used as positions, and arithmetic done on them. It is proposed that the index of a list item be of class `OBJECT` rather than of class `STRING`. In OOI, the `.ENVIRONMENT` is global, not read-only, and contains builtin objects such as `.TRUE` and `.FALSE`. The committee regards this as too risky - suppose that `.TRUE` was accidentally or maliciously revalued as 0!

It seems sufficient to add read-only as a characteristic of directories. (This characteristic at the element level might be expensive to implement.)

Reserved symbols (X8-274 clause 6.2.3.1) also provide a mechanism for preventing the override of builtin names.

It won't be possible for a standard to exactly define in a system-independent way the scopes/lifetimes of `.ENVIRONMENT` and `.LOCAL` but (as with OOI) the `.LOCAL` will relate to "One API\_START" and `.ENVIRONMENT` will have a wider scope. (Power on to power off of some system?).

The proposed "search order" is:

1. Things provided by the system which no user is expected to want to override. Perhaps `.TRUE` `.FALSE` `NIL`.
2. The `.LOCAL` read/write directory, initialized with the default streams, changable by the user for individual program executions. Perhaps `METHODS` here.
3. The read-only part of the environment, that is the builtin classes and objects. Also `.SYSTEM` perhaps.
4. The read/write `.ENVIRONMENT` directory. Changable by programmers co-operating at the system level.

Final placement of all builtins needs discussion, but the read-only true&false requirement will be met. Note that the algorithm of method lookup does not change if "old objects see newest methods" is desired. What changes is whether the method tables are updated in place or copied-and-updated when they are changed.

1. There have been suggestions to allow the `REQUIRES` directive appear in more places. The committee agrees with this and proposes:

- A) All REQUIRES directives must appear together in the file.
  - B) These directives may appear anywhere the OOI implementation currently allows them to appear.
2. Message numbers and prose are now allocated to messages detected by the syntax, additional to the messages known to the first standard. Most messages simply involve new minor codes sequential beyond those defined in the first standard.
  3. Proposed language, eg FORWARD, METHOD, and CLASS clauses, allow for many options which can appear in any order. These can be written in the BNF (in the manner that TO BY FOR were handled in the first standard) but it is neater to extend the BNF metalanguage.
  4. The OOI syntax used in the FORWARD instruction has examples of the 'argument' construct, which is either a symbol-or-string taken as a constant or is an expression in parentheses. The committee will define 'term' to be allowed in such places. This is a change to the OOI for valid programs only in the case where a MESSAGE option used a symbol intending it to be 'taken as a constant'. (As opposed to taken as a variable with the value defaulting to its name when uninitialized.)
  5. In a similar vein to 4 above, some other positions where the "variable reference" notation is used (or proposed) will be changed. It would be nice to allow "term" in all these places but ambiguity consideration means some will be "sub-expression", ie parenthesed expression, notation.
  6. The colon used for superclass specification will allow symbol-or-string to follow. DATA:
  7. The model of data used in defining the first standard needs changing for OO, to:
    - Variable pools are objects, objects are variable pools.
    - Variable pool contents are references to objects, not values of strings.
    - Pools are not numbered, they are referenced.
    - The state variables (those with names beginning '#' used to define processing in the standard) are present in all pools, as opposed to being in a separate pool.

This data model gives a natural interpretation to the variable pool API applied to local pools. (Local pools may access non-local pool items by reason of EXPOSE.)

In principle this leads to different threads of execution (resulting from REPLY) being able to execute the API. (In practice OOI has a restriction to executing the API only on the 'main' thread and the committee needs to know if this is due to a generally applicable difficulty.)

The committee considered the relevance of IBM's "Object REXX Programming Guide" G25H-7597-1 to the Configuration section of the standard. The material there in Appendix A under headings External Function Interface, System Exit Interface, and Variable Pool Interface was deemed material for inclusion, and the rest not. This is similar to the first standard, although there will be an extra trap, for method calls. The committee considered the relevance of the STREAM section of IBM's "Object REXX Reference", G25H-7598-0. That stream class brings into the language more I/O than the original REXX, eg an explicit CLOSE. The new standard will partially follow this trend also.

PEEK on queue unnecessary - same as AT[1]?

*Also need to resolve the issues on Monitor class and on run time inspection.*

## Annex B

(informative)

Method of definition

This annex describes the methods chosen to describe Rexx for this standard.

Definitions

Definitions are given for some terms which are both used in this standard and also may be used elsewhere. This does not include names of syntax constructions; for example, group, which are distinguished in this standard by the use of italic font.

Conformance

Note that irrespective of how this standard is written, the obligation on a conforming processor is only to achieve the defined results, not to follow the algorithms in this standard.

Notation

The notation used to describe functions provided by the configuration is like a Rexx function call but it is not defined as a Rexx function call since a Rexx function call is described in terms of one of these configuration functions.

Note that the mechanism of a returned string with a distinguishing first character is part of the notation used in this standard to explain the functions; implementations may use a different mechanism. Notation for completion response and conditions

The testing of 'X' and 'S' indicators is made implicit, for brevity. Even when written as a subroutine call, each use of a configuration routine implies the testing. Thus:

call Config Time

implies

#Response = Config Time()

if left (#Response,1) == 'X' then call #Raise 'SYNTAX', 5.1, substr (#Response, 2) if left (#Response,1) == 'S' then call #Raise 'SYNTAX', 48.1, substr(#Response, 2)

Source programs and character sets

The characters required by Rexx are identified by name, with a glyph associated so that they can be printed in this standard. Alternative names are shown as a convenience for the reader.

Notation

Note that nnn is not specifying the syntax of a program; it is specifying the notation used in this standard for describing syntax.

## Lexical level

Productions `nnn` and `nnn` contain a recursion of comment. Apart from this recursion, the lexical level is a finite state automaton.

## Syntax level

This syntax shows a `null_clause` list, which is minimally a semicolon, being required in places where programmers do not normally write semicolons, for example after `'THEN'`. This is because the `'THEN'` implies a semicolon. This approach to the syntax was taken to allow the rule `'semicolons separate clauses'` to define `'clauses'`.

The precedence rules for the operators are built into this grammar

## Data Model

The following explanation of data in terms of Classic Rexx may be helpful. References to clauses of the existing standard have 274 as a prefix.

We start with the data model from the first Standard - a number of variable pools. Two mechanisms, the external access of section 274.5.13 (`API_Drop` etc) and the internal of 274.7.1 (`Var_Drop` etc). Pools are numbered, with pool 0 reserved for reserved names (`.MN` etc) and pool `N-1` being related to pool `N` as the caller's pool. The symbols which index the pools are distinguished as tailed or non-tailed. The items in the pool have attributes `'exposed'`, `'dropped'`, and `'implicit'`. The values in the pools are string values.

An extra scope is used for `'state variables'` used in the definition of the standard. These follow the same lookup rules in a conceptual and separate pool.

The first change necessary is to define the values in the pools as references. For string values this is just a change in definition style, since a reference always followed to a string value is semantically identical with the notion of having the value in the pool. However, references open the possibility of referencing

non-strings, which can behave in a changed way while still being referred to by the same reference. (Mutable objects)

It is reasonable that the definition should have the pools reference one another rather than use numbered pools. It is difficult to have a notion of numbering the pools when any object can have a set of variables associated with it.

Assignment is defined as assignment of references. The language could have been designed differently, for example to make assignment behave like the `COPY` method, but assignment of references is the natural, powerful, choice.

If pools are not numbered, the notation of the first standard, where some state variables use the `#Level` number as part of their names, will not suffice. An appropriate solution is to say that each variable pool can have state variables and user program variables in it. Placing the state variables that are per-procedure-level in the variable pool for their level avoids the need to specify `#Level` in their tails. There are pre-existing objects such as all possible values that can be written as literals and the objects accessed by `.SYSTEM` etc. Further objects are created by the `NEW` method.

Editorial note: It looks nice to unify: an object *is* a variable pool and a variable pool *is* an object. There is some awkwardness describing the classic `API_` function as applying to an object. There don't seem to be difficulties in defining any object behaviour we want in terms of state variables that refer from one object to another.

Evaluation (Definitions written as code) There is no single definitional mechanism for describing semantics that is predominantly used in standards describing programming languages, except for the use of prose. The committee has chosen to define some parts of this standard using algorithms written in Rexx. This has the advantages of being rigorous and familiar to many of the intended readers of this standard. It has the potential disadvantage of circularity - a definition based on an assumption that the reader already understands what is being defined. Circularity has been avoided by: - specifying the language incrementally, so that the algorithms for more complex details are specified in code that uses only more simple Rexx. For example, the notion that an expression evaluates to a result can be understood by the reader even without a complete specification of all operators and built-in functions that might be used in the expression; - specifying the valid syntax of Rexx programs without using Rexx coding. The method used, Backus Normal Form, can adequately be introduced by prose. Ultimately, some understanding of programming languages is assumed in the reader (just as the ability to read prose is assumed) but any remaining circularity in this standard is harmless. The comparison of two single characters is an example of such a circularity; Config\_Compare can compare two characters but the outcome can only be tested by comparing characters. It has to be assumed that the reader understands such a comparison. Some of the definition using code is repeating earlier definition in prose. This duplication is to make the document easier to understand when read from front to back. Note that the layout of the code, in the choices of instructions-per-line, indentations etc., is not significant. (The layout style used follows the examples in the base reference and it is deliberate that the DO and END of a group are not at the same alignment.) The code is not intended as an example of good programming practice or style. The variables in this code cannot be directly referenced by any program, even if the spelling of some VAR\_SYMBOL coincides. These variables, referred to as state variables, are referenced throughout this document; they are not affected by any execution activity involving scopes. Some of more significant variables and routines are written with # as their first character. The following list of them is intended as an aid to understanding the code. The index of this standard shows the main usage, but not all usage, of these names. The following are constants set by the configuration, by Config\_Constants: #Configuration is used for PARSE SOURCE. #Version is used for PARSE VERSION. #Bif\_Digits. represents numeric digits settings, tails are built-in function names. #Limit\_Digits is the maximum significant digits. #Limit\_EnvironmentName is a maximum length.

#Limit\_ExponentDigits is the maximum digits in an exponent. #Limit\_Literal is a maximum length.

#Limit\_MessageInsert is a maximum length.

#Limit\_Name is a maximum length.

#Limit\_String is a maximum length.

#Limit\_TraceData is a maximum length.

These are named outputs of configuration routines:

#Response is used to hold the result from a configuration routine. #Indicator is used to hold the leftmost character of Response. #Outcome is the main outcome of a configuration routine.

#RC is set by Contig\_Command.

#NoSource is set by Config\_NoSource.

#Time is set by Config\_Time

#Adjust<Index “#Adjust” #“ ”> is set by Config\_Time

These variables are set up with output from configuration routines:

#HowInvoked records from API\_Start, for use by PARSE SOURCE.

#Source records from API\_Start for use by PARSE SOURCE.

#AllBlanks<Index “#AllBlanks” #“ ”> is a string including Blank and equivalents.

#ErrorText.MsgNumber is the text as altered by limits.

#SourceLine. is a record of the source, retained unless NoSource is set. #SourceLine.0 is a count of lines.

#Pool is a reference to the current variable pool.

These are variables not initialized from the configuration:

#Level is a count of invocation depth, starting at one.

#NewLevel equals #Level plus one.

#Pool1 is a reference to the variable pool current when the first instruction was executed.

#Upper is a reference to the variable pool which will be current when the current PROCEDURE ends. #Loop is a count of loop nesting.

#LineNumber is the line number of the current clause.

#Symbol is a symbol after tails replacement.

#API\_Enabled determines when the application programming interface for variable pools is available. #Test is the Greater/Lesser/Equal result.

#InhibitPauses is a numeric trace control.

#InhibitTrace is a numeric trace control.

#AtPause is on when executing interactive input.

#AllowProcedure provides a check for the label needed before a procedure.

#DatatypeResult is a by-product of DATATYPE().

#Condition is a condition, eg 'SYNTAX'.

#Trace\_QueryPrior detects an external request for tracing.

#TraceInstruction detects TRACE as interactive input.

These are variables that are per-Level, that is, have #Level as a tail component:

#IsFunction. indicates a function call.

#IsProcedure. indicates indicates the routine is a procedure.

#Condition. indicates whether the routine is handling a condition.

#ArgExists.#Level.ArgNumber indicates whether an argument exists. (Initialized from API\_Start for Level=1)

#Arg.#Level.ArgNumber provides the value of an argument. (Initialized from API\_Start for Level=1) When ArgNumber=0 this gives a count of the arguments.

#Tracing. is the trace setting letter.

#Interactive. indicates when tracing is interactive. ('?' trace setting) #ClauseLocal. ensures that DATE/TIME are consistent across a clause. #ClauseTime. is the TIME/DATE frozen for the clause.

#StartTime. is for 'Elapsed' time calculations.

#Digits. is the current numeric digits.

#Form. is the current numeric form.

#Fuzz. is the current numeric fuzz.

These are qualified by #Condition as well as #Level:

#Enabling. is 'ON', 'OFF' or 'DELAYED'.

#Instruction. is 'CALL' or 'SIGNAL'

#TrapName. is the label.

#ConditionDescription. is for CONDITION('D')

#ConditionExtra. is for CONDITION('E')

#ConditionInstruction. is for CONDITION('T')

#PendingNow. indicates a DELAYED condition. #PendingDescription. is the description of a DELAYED condition. #PendingExtra. is the extra description for a DELAYED condition. #EventLevel. is the #Level at which an event was DELAYED.

These are qualified by ACTIVE, ALTERNATE, or TRANSIENT as well as #Level:

#Env\_Name. is the environment name.

#Env\_Type. is the type of a resource, and is additionally qualified by input/output/error distinction. #Env\_Resource. is the name of a resource, and is additionally qualified by input/output/error distinction. #Env\_Position. is INPUT or APPEND or REPLACE, and is additionally qualified by input/output/error distinction.

These are variables that are per-loop:

#Identity. is the control variable.

#Repeat. is the repetition count.

#By. is the increment.

#To. is the limit.

#For. is that count.

#Iterate. holds a position in code describing DO instruction semantics. #Once. holds a position in code describing DO instruction semantics.

#Leave. holds a position in code describing DO instruction semantics.

These are variables that are per-stream:

#Charin\_Position.

#Charout\_Position.

#Linein\_Position.

#Lineout\_Position.

#StreamState. records ERROR state for return by STREAM built-in function.

These are commonly used prefixes: Config\_ is used for a function provided by the configuration. API\_ is used for an application programming interface.

Trap\_ is used for a routine called from the processor, not provided by it. Var\_ is used for the routines operating on the variable pools.

These are notation routines, only available to code in this standard:

#Contains checks whether some construct is in the source. #Instance returns the content of some construct in the source. #Evaluate returns the value of some construct in the source. #Execute causes execution of some construct in the source. #Parses checks whether a string matches some construct. #Clause notes some position in the code.

#Goto continues execution at some noted position.

#Retry causes execution to continue at a previous clause.

These are frequently used routines: #Raise is a routine for condition raising. #Trace is a routine for trace output.

#TraceSource is a routine to trace the source program. #CheckArgs processes the arguments to a built-in function.

---

## Acknowledgments

RexxLA thanks everybody who has been involved with the REXX symposia over more than 30 years. Mike Cowlshaw for being the Father of REXX, Rick McGuire for being the driving force behind all IBM implementations of REXX, Chip Davis who is Past-President for Life, Mark Hessling for maintaining Regina and building our wonderful symposium application and web site (which enable this publication). Simon Nash for being the architect of Oryx, which became Object Rexx. Jon Wolfers for all his work in converting the website to the database-driven system, and being our treasurer. Gil Barmwater for being our vice-president and treasurer for many years. Rony Flatscher for his teaching and enthusiasm, and for connecting ooRexx to the Java Virtual Machine and its libraries. All the presenters for investing their time to deliver the message. Terry Fuller for being the current vice-president and his help during the symposia. Lee Peedin for his work as President and Vice President for many years. Cathie Dager for being a REXX “Spark Plug”, Pam Taylor for all her work for RexxLA. Virgil Hein and Matthew Emmons for being our representatives within IBM and assisting us through the open sourcing of the IBM products. We thank IBM for graciously donating two of their REXX implementations, Object Rexx and NetRexx, to RexxLA and the open source community. We thank Per-Olov Jonsson for financing and running our automated test facility - and for all his work on that very important environment. David Ashley his contributions in the early days of “Open” Object Rexx. Marc Remes for saving NetRexx from the Java Platform Modules System. Erich Steinbock and Jean-Louis Faucher for their contributions (and future contributions) to ooRexx.

RexxLA remembers our departed, Kurt Maerker, Brian Marks, Les Koehler, Mark Miesfeld, Oliver Sims and Kermit Kiser, for all their work and pleasant company.
